Abstract

Ontologies and datasets for the Semantic Web are encoded in OWL formalisms that are not easily comprehended by people. To make ontologies accessible to human domain experts, several research groups have developed ontology verbalisers using Natural Language Generation. In practice ontologies are usually composed of simple axioms, so that realising them separately is relatively easy; there remains however the problem of producing texts that are coherent and efficient. We describe in this paper some methods for producing sentences that aggregate over sets of axioms that share the same logical structure. Because these methods are based on logical structure rather than domain-specific concepts or language-specific syntax, they are generic both as regards domain and language.

1 Introduction

When the Semantic Web becomes established, people will want to build their own knowledge bases (i.e., ontologies, or TBox axioms, and data, or ABox axioms1). Building these requires a high level of expertise and is time-consuming, even with the help of graphical interface tools such as Protégé (Knublauch et al., 2004). Fortunately, natural language engineers have provided a solution to at least part of the problem: verbalisers, e.g., the OWL ACE verbaliser (Kaljurand and Fuchs, 2007).

Ontology verbalisers are NLG systems that generate controlled natural language from Semantic Web languages, see Smart (2008). Typically they generate one sentence per axiom: for example, from the axiom2 `\texttt{Cat} \sqsubseteq \texttt{Animal}` the OWL ACE verbaliser (Kaljurand and Fuchs, 2007) generates ‘Every cat is an animal’. The result is not a coherent text, however, but a disorganised list, often including inefficient repetitions such as:

- Every cat is an animal.
- Every dog is an animal.
- Every horse is an animal.
- Every rabbit is an animal.

An obvious first step towards improved efficiency and coherence would be to replace such lists with a single aggregated sentence:

The following are kinds of animals: cats, dogs, horses and rabbits.

In this paper, we show how all axiom patterns in $\mathcal{EL}^{++}$, a DL commonly used in the Semantic Web, can be aggregated \textit{without further domain knowledge}, and describe a prototype system that performs such aggregations. Our method aggregates axioms \textit{while they are still in logical form}, i.e., as part of sentence planning but before converting to a linguistic representation and realising as English sentences. This approach is somewhat different from that proposed by other researchers who convert ontology axioms to linguistic structures before aggregating (Hielkema, 2009; Galanis et al., 2009; Dongilli, 2008). We present results from testing our algorithm on over fifty ontologies from the Tones repository3.

2 Analysis of Axiom Groupings

In this section we analyse which kinds of axioms might be grouped together. Power (2010) anal-

1

\[ \text{Functional Syntax: } \text{subClassOf}((\text{class}(\text{ns:cat}) \text{class}(\text{ns:animal})) \text{where ns is any valid namespace. The operator } \sqsubseteq \text{ denotes the subclass relation, } \cap \text{ denotes class inter\-section, and } \exists P.C \text{ the class of individuals bearing the relation } P \text{ to one or more members of class } C. \]

2

http://owl.cs.manchester.ac.uk/
There are two techniques with which to aggregate them: merging and chaining. If the right-hand sides are identical we can merge the left-hand sides, and vice versa.\(^4\)

\[
\begin{align*}
[A,B] &\subseteq C \\
A &\subseteq [B,C]
\end{align*}
\]

Alternatively, where the right-hand side of an axiom is identical to the left-hand side of another axiom, we can ‘chain’ them:

\[
A \sqsubseteq B \sqsubseteq C \sqsubseteq D
\]

Merging compresses the information into a more efficient text, as shown in the introduction, while chaining orders the information to facilitate inference — for example, ‘Every A is a B and every B is a C’ makes it easier for readers to draw the inference that every A is a C.

\(^4\)We regard expressions like \(A \sqsubseteq [B,C]\) and \(A \sqsubseteq B \sqsubseteq C\) as shorthand forms allowing us to compress several axioms into one formula. For merges one could also refactor the set of axioms into a new axiom: thus for example \(A \sqsubseteq [B,C]\) could be expressed as \(A \sqsubseteq (B \cap C)\), or \([A,B] \subseteq C\) as \((A \cup B) \subseteq C\). This formulation would have the advantage of staying within the normal notation and semantics of DL; however, it is applicable only to merges, not to chains.

Table 1: The four most common axiom patterns.

<table>
<thead>
<tr>
<th>No.</th>
<th>Logic</th>
<th>OWL</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(A \sqsubseteq B)</td>
<td>subClassOf(A, B)</td>
<td>51</td>
</tr>
<tr>
<td>2</td>
<td>(A \sqsubseteq \exists P.B)</td>
<td>subClassOf(A, someValuesFrom(P, B))</td>
<td>33</td>
</tr>
<tr>
<td>3</td>
<td>([a,b] \in P)</td>
<td>propertyAssertion(P, a b)</td>
<td>8</td>
</tr>
<tr>
<td>4</td>
<td>(a \in A)</td>
<td>classAssertion(A, a)</td>
<td>4</td>
</tr>
</tbody>
</table>

Table 2 summarises our conclusions on whether each pair of the four common patterns can be merged or chained. Each cell contains three entries, indicating the possibility of left-hand-side merge (L), right-hand-side merge (R), and chaining (C).

Table 2: Aggregating common axioms: 1. \(A \sqsubseteq B\), 2. \(A \sqsubseteq \exists P. B\), 3. \([a,b] \in P\), 4. \(a \in A\)

\[
\begin{array}{cccc}
1 & 2 & 3 & 4 \\
L, R, C & \times, R, \times & \times, \times, \times & \times, L, \times \\
\end{array}
\]

Table 3: Generic merging rules.

<table>
<thead>
<tr>
<th>Function</th>
<th>Merge Patterns</th>
</tr>
</thead>
<tbody>
<tr>
<td>(f_1(A))</td>
<td>(f_1((A_1, A_2, A_3, \ldots)))</td>
</tr>
<tr>
<td>(f_2(A, B))</td>
<td>(f_2(A, [A_1, B_1, B_2, B_3, \ldots]))</td>
</tr>
<tr>
<td>(f_3(A, B, C))</td>
<td>(f_3(A, [A_1, A_2, A_3, \ldots] B, C))</td>
</tr>
<tr>
<td>(f_4(A, B, C))</td>
<td>(f_4(A, B, [C_1, C_2, C_3, \ldots]))</td>
</tr>
</tbody>
</table>

In general, we combine axioms for which the functor is the same and only one argument differs. We do not aggregate axiom functions with more than three arguments. The merged constituents must be different expressions with the same logical form.

4 Implemention

This section describes a Prolog application which performs a simple verbalisation including aggregation. It combines a generic grammar for realising logical forms with a domain-specific lexicon.
derived from identifiers and labels within the input ontology.

Input to the application is an OWL/XML file. Axioms that conform to \( \mathcal{EL}^{++} \) are selected and converted into Prolog format. A draft lexicon is then built automatically from the identifier names and labels, on the assumption that classes are lexicalised by noun groups, properties by verb groups with valency two, and individuals by proper nouns.

Our aggregation rules are applied to axioms with the same logical form. The first step picks out all the logical patterns present in the input ontology by abstracting from atomic terms. The next step searches for all axioms matching each of the patterns present. Then within each pattern-set, the algorithm searches for axioms that differ by only one argument, grouping axioms together in the ways suggested in table 3. It exhaustively lists every possible grouping and builds a new, aggregated axiom placing the values for the merged argument in a list, e.g., consider the axioms:

\[
\begin{align*}
\text{subClassOf}(\text{class(cat)}, \text{class(feline)}). \\
\text{subClassOf}(\text{class(cat)}, \text{class(mammal)}). \\
\text{subClassOf}(\text{class(dog)}, \text{class(mammal)}). \\
\text{subClassOf}(\text{class(mouse)}, \text{class(mammal)}).
\end{align*}
\]

Identical first arguments \( \Rightarrow \)

\[
\begin{align*}
\text{subClassOf}(\text{class(cat)}, \\
[ \text{class(feline)}, \\
\text{class(mammal)} ]).
\end{align*}
\]

‘Every cat is a feline and a mammal.’

Identical second arguments \( \Rightarrow \)

\[
\begin{align*}
\text{subClassOf}([ \text{class(cat)}, \text{class(dog)}, \\
\text{class(mouse)} ], \text{class(mammal)}).
\end{align*}
\]

‘The following are kinds of mammal: cats, dogs and mice.’

For all axioms with an identical first argument, \text{class(cat)}, the algorithm places the second arguments in a list, \([ \text{class(feline)}, \text{class(mammal)} ]\), and builds a new axiom with the first argument and the merged second argument. From this, our realiser generates the sentence ‘Every cat is a feline and a mammal.’ A similar process is performed on first arguments when the second arguments are identical.

To construct the grammar, we first formulated rules for realising single axioms, and then added rules for the aggregated patterns, incorporating aggregation cues such as ‘both’ and ‘the following’: (Dalianis and Hovy, 1996). For the wording of single axioms we relied mainly on proposals from the OWL Controlled Natural Language task force (Schwitter et al., 2008), so obtaining reasonably natural sentences for common axiom patterns, even though some less common axioms such as those describing attributes of properties (e.g., domain, range, functionality, reflexivity, transitivity) are hard to express without falling back on technical concepts from the logic of relations; for these we have (for now) allowed short technical formulations (e.g., ‘The property “has as part” is transitive’). With these limitations, the grammar currently realises any single axiom conforming to \( \mathcal{EL}^{++} \), or any aggregation of \( \mathcal{EL}^{++} \) axioms through the merge rules described above. Table 4 lists example aggregated axiom patterns and English realisations generated with our grammar.

## 5 Testing the ‘Merging’ Algorithm

Table 5: Reduction achieved by aggregating

<table>
<thead>
<tr>
<th>Unit</th>
<th>Original</th>
<th>Aggregated</th>
<th>Reduction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sentences</td>
<td>35,542</td>
<td>11,948</td>
<td>66%</td>
</tr>
<tr>
<td>Words</td>
<td>320,603</td>
<td>264,461</td>
<td>18%</td>
</tr>
</tbody>
</table>

We have tested our generic merging rules on axioms conforming to \( \mathcal{EL}^{++} \) in a sample of around 50 ontologies. Table 5 shows the reduction in the number of generated sentence after aggregation. Remember that previously, the system generated one sentence for every axiom (35,542 sentences), but with aggregation this is reduced to 11,948 sentences, an overall reduction of 66%. However, aggregation increases sentence length so the saving in words is only 18%.

The effect of merging is to replace a large number of short sentences with a smaller number of longer ones. Sometimes the aggregated sentences were very long indeed, e.g., when a travel ontology cited 800 instances of the class \text{island} — perhaps such cases would be expressed better by a table than by prose\(^6\).

The algorithm computes all possible merges, so we get, for instance, Fred described as a person in both ‘The following are people: Fred, . . . ’ and ‘Fred is all of the following: a person, . . . ’. This means that the greater efficiency achieved through aggregation may be counterbalanced by the extra text required when the same axiom participates in several merges — for a few of our ontologies, in

\( ^6 \)In a summary one might instead simply give a count and an example: ‘There are 800 islands, e.g., The Isle of Skye’.
fact, the word count for the aggregated version was greater. This is an interesting problem that we have not seen treated elsewhere. Merely pursuing brevity, one might argue that an axiom already included in a merge should be removed from any other merges in which it participates; on the other hand, the arbitrary exclusion of an axiom from a list might be regarded as misleading. For now we have allowed repetition, leaving the problem to future work.

6 Related Work

Reape and Mellish’s (1999) survey of aggregation in NLG proposed a continuum of definitions ranging from narrow to wide. Our technique fits into the narrow definition, i.e., it is language-independent, operating on non-linguistic conceptual representations with the aim of minimising redundancy and repetition. It implements the subject and predicate grouping rules and aggregation cues suggested by Dalianis and Hovy (1996).

Recent NLG systems that aggregate data from ontologies (Hielkema, 2009; Galanis and Androutsopoulos, 2007; Dongilli, 2008) do not perform aggregation directly on axioms, but only after converting them to linguistic representations. Moreover, their systems generate only from ABox axioms in restricted domains while ours generates English for both ABox and TBox in any domain.

The approach most similar to ours is that of Bontcheva and Wilks (2004), who aggregate a subset of RDF triples after domain-dependent discourse structuring — a task equivalent to merging axioms that conform to the objectPropertyAssertion pattern in table 4.

7 Conclusion

We have demonstrated that for the $\mathcal{EL}++$ DL that underlies many Semantic Web ontologies we can define generic aggregation rules based on logical structure, each linked to a syntactic rule for expressing the aggregated axioms in English. The work described here is a first step in tackling a potentially complex area, and relies at present on several intuitive assumptions that need to be confirmed empirically. First, from an examination of all combinations of the four commonest axiom patterns, we concluded that axioms sharing the same pattern could be combined more effectively than axioms with different patterns, and therefore focussed first on same-pattern merges with variations in only one constituent. Secondly, after systematically enumerating all such merges for $\mathcal{EL}++$, we have implemented a grammar that expresses each aggregated pattern in English, relying on an intuitive choice of the best form of words: at a later stage we need to confirm that the resulting sentences are clearly understood, and to consider whether different formulations might be better.
