Abstract
This short paper introduces an implemented and evaluated monolingual Text-to-Text generation system. The system takes monologue and transforms it to two-participant dialogue. After briefly motivating the task of monologue-to-dialogue generation, we describe the system and present an evaluation in terms of fluency and accuracy.

1 Introduction
Several empirical studies show that delivering information in the form of a dialogue, as opposed to monologue, can be particularly effective for education (Craig et al., 2000; Lee et al., 1998) and persuasion (Suzuki and Yamada, 2004). Information-delivering or expository dialogue was already employed by Plato to communicate his philosophy. It is used primarily to convey information and possibly also make an argument; this in contrast with dramatic dialogue which focuses on character development and narrative.

Expository dialogue lends itself well for presentation through computer-animated agents (Prendinger and Ishizuka, 2004). Most information is however locked up as text in leaflets, books, newspapers, etc. Automatic generation of dialogue from text in monologue makes it possible to convert information into dialogue as and when needed.

This paper describes the first data-oriented monologue-to-dialogue generation system which relies on the automatic mapping of the discourse relations underlying monologue to appropriate sequences of dialogue acts. The approach is data-oriented in that the mapping rules have been automatically derived from an annotated parallel monologue/dialogue corpus, rather than being hand-crafted.

The paper proceeds as follows. Section 2 reviews existing approaches to dialogue generation. Section 3 describes the current approach. We provide an evaluation in Section 4. Finally, Section 5 describes our conclusions and plans for further research.

2 Related Work
For the past decade, generation of information-delivering dialogues has been approached primarily as an AI planning task. Andrè et al. (2000) describe a system, based on a centralised dialogue planner, that creates dialogues between a virtual car buyer and seller from a database; this approach has been extended by van Deemter et al. (2008). Others have used (semi-) autonomous agents for dialogue generation (Cavazza and Charles, 2005; Mateas and Stern, 2005).

More recently, first steps have been taken towards treating dialogue generation as an instance of Text-to-Text generation (Rus et al., 2007). In particular, the T2D system (Piwek et al., 2007) employs rules that map text annotated with discourse structures, along the lines of Rhetorical Structure Theory (Mann and Thompson, 1988), to specific dialogue sequences. Common to all the approaches discussed so far has been the manual creation of generation resources, whether it be mappings from knowledge representations or discourse to dialogue structure.
With the creation of the publicly available\footnote{computing.open.ac.uk/coda/data.html} CODA parallel corpus of monologue and dialogue (Stoyanchev and Piwek, 2010a), it has, however, become possible to adopt a data-oriented approach. This corpus consists of approximately 700 turns of dialogue, by acclaimed authors such as Mark Twain, that are aligned with monologue that was written on the basis of the dialogue, with the specific aim to express the same information as the dialogue.\footnote{Consequently, the corpus was not constructed entirely of pre-existing text; some of the text was authored as part of the corpus construction. One could therefore argue, as one of the reviewers for this paper did, that the approach is not entirely data-driven, if data-driven is interpreted as ‘generated from unaltered, free text, without any human intervention needed’. For step I we rely on human annotation or existing discourse parsers such as DAS (Le and Abeysinghe, 2003) and HILDA (duVerle and Prendinger, 2009). For the current study, the final step, V, consists simply of verbatim presentation of the dialogue text. The focus of the current paper is with steps II and III (with combination, step IV, beyond the scope of the current paper). Step II is data-oriented in that we have extracted mappings from discourse relation occurrences in the corpus to corresponding dialogue act sequences, following the approach described in Piwek and Stoyanchev (2010). Stoyanchev and Piwek (2010b) observed in the CODA corpus a great variety of Dialogue Act (DA) sequences that could be used in step II, however in the current version of the system we selected a representative set of the most frequent DA sequences for the five most common discourse relations in the corpus. Table 1 shows the mapping from text with a discourse relations to dialogue act sequences (i indicates implemented mappings).

Table 1: Mappings from discourse relations (A = Attribution, CD = Condition, CT = Contrast, ER = Explanation-Reason, MM = Manner-Means) to dialogue act sequences (explained below) together with the type of verbalisation transformation TR being d(irect) or c(omplex).

For comparison, the table also shows the much less varied mappings implemented by the T2D system (indicated with t). Note that the actual mappings of the T2D system are directly from discourse relation to dialogue text. The dialogue acts are not explicitly represented by the system, in contrast with the current two stage approach which distinguishes between relation conversion and verbalisation.

3 Monologue-to-Discourse Generation Approach

Our approach is based on five principal steps:

I \textit{Discourse parsing}: analysis of the input monologue in terms of the underlying discourse relations.

II \textit{Relation conversion}: mapping of text annotated with discourse relations to a sequence of dialogue acts, with segments of the input text assigned to corresponding dialogue acts.

III \textit{Verbalisation}: verbal realisation of dialogue acts based on the dialogue act type and text of the corresponding monologue segment.

IV \textit{Combination} Putting the verbalised dialogues acts together to create a complete dialogue, and

V \textit{Presentation}: Rendering of the dialogue (this can range for simple textual dialogue scripts to computer-animated spoken dialogue).
Verbalisation, step III, takes a dialogue act type and the specification of its semantic content as given by the input monologue text. Mapping this to the appropriate dialogue act requires mappings that vary in complexity.

For example, $\text{Expl(ain)}$ can be generated by simply copying a monologue segment to dialogue utterance. The dialogue acts $\text{Yes}$ and $\text{Agreement}$ can be generated using canned text, such as “That is true” and “I agree with you”.

In contrast, $\text{ComplQ}$ (Complex Question), $\text{FactQ}$ (Factoid Question), $\text{FactA}$ (Factoid Answer) and $\text{YNQ}$ (Yes/No Question) all require syntactic manipulation. To generate $\text{YNQ}$ and $\text{FactQ}$, we use the CMU Question Generation tool (Heilman and Smith, 2010) which is based on a combination of syntactic transformation rules implemented with trexeg (Levy and Andrew, 2006) and statistical methods. To generate the $\text{Compl(ex) Q(uestion)}$ in the $\text{ComplQ; Expl}$ Dialogue Act (DA) sequence, we use a combination of the CMU tool and lexical transformation rules. The GEN example in Table 2 illustrates this: The input monologue has a Manner-Means relations between the nucleus ‘In September, Ashland settled the long-simmering dispute’ and the satellite ‘by agreeing to pay Iran 325 million USD’. The satellite is copied without alteration to the Explain dialogue act. The nucleus is processed by applying the following template-based rule:

$$\text{Decl} \Rightarrow \text{How Yes/No Question(Dcl)}$$

In words, the input consisting of a declarative sentence is mapped to a sequence consisting of the word ‘How’ followed by a Yes/No-question (in this case “Did Ashland settle the long-simmering dispute in December?”) that is obtained with the CMU QG tool from the declarative input sentence. A similar approach is applied for the other relations (Attribution, Condition and Explanation-Reason) that can lead to a $\text{ComplQ; Expl}$ dialogue act sequence (see Table 1).

Generally, sequences requiring only copying or canned text are labelled $\text{d(irect)}$ in Table 1, whereas those requiring syntactic transformation are labelled $\text{c(omplex)}$.

### 4 Evaluation

We evaluate the output generated with both complex and direct rules for the relations of Table 1.

#### 4.1 Materials, Judges and Procedure

The input monologues were text excerpts from the Wall Street Journal as annotated in the RST Discourse Treebank$^4$. They consisted of a single sentence with one internal relation, or two sentences (with no internal relations) connected by a single relation. To factor out the quality of the discourse annotations, we used the gold standard annotations of the Discourse Treebank and checked these for correctness, discarding a small number of incorrect annotations.$^5$ We included text fragments with a variety of clause length, ordering of nucleus and satellite, and syntactic structure of clauses. Table 2 shows examples of monologue/dialogue pairs: one with a generated dialogue and the other from the corpus.

Our study involved a panel of four judges, each fluent speakers of English (three native) and experts in Natural Language Generation. We collected judgements on 53 pairs of monologue and corresponding dialogue. 19 pairs were judged by all four judges to obtain inter-annotator agreement statistics, the remainder was parcelled out. 38 pairs consisted of WSJ monologue and generated dialogue, henceforth GEN, and 15 pairs of CODA corpus monologue and human-authored dialogue, henceforth CORPUS (instances of generated and corpus dialogue were randomly interleaved) – see Table 2 for examples.

The two standard evaluation measures for language generation, accuracy and fluency (Mellish and Dale, 1998), were used: a) $\text{accuracy}$: whether a dialogue (from GEN or CORPUS) preserves the information of the corresponding monologue (judgement: ‘Yes’ or ‘No’) and b) $\text{monologue and dialogue fluency}$: how well written a piece of monologue or dialogue from GEN or CORPUS is. Fluency judgements were on a scale from 1 ‘incomprehensible’ to 5 ‘Comprehensible, grammatically correct and naturally sounding’.

---

$^3$In contrast, the $\text{ComplQ}$ in the DA sequence $\text{Expl;ComplQ;Expl}$ is generated using canned text such as ‘Why?’ or ‘Why is that?’.

$^4$www.isi.edu/~marcu/discourse/Corpora.html

$^5$For instance, in our view ‘without wondering’ is incorrectly connected with the attribution relation to ‘whether she is moving as gracefully as the scenery.’
In September, Ashland settled the long-simmering dispute by agreeing to pay Iran 325 million USD.

**Dialogue (ComplQ; Expl)**
A: How did Ashland settle the long-simmering dispute in December?
B: By agreeing to pay Iran 325 million USD.

If you say “I believe the world is round”, the “I” is the mind.

**Dialogue (FactQ; FactA)**
A: If you say “I believe the world is round”, who is the “I” that is speaking?
B: The mind.

### 4.2 Results

**Accuracy** Three of the four judges marked 90% of monologue-dialogue pairs as presenting the same information (with pairwise $\kappa$ of .64, .45 and .31). One judge interpreted the question differently and marked only 39% of pairs as containing the same information. We treated this as an outlier, and excluded the accuracy data of this judge. For the instances marked by more than one judge, we took the majority vote. We found that 12 out of 13 instances (or 92%) of dialogue and monologue pairs from the CORPUS benchmark sample were judged to contain the same information. For the GEN monologue-dialogue pairs, 28 out of 31 (90%) were judged to contain the same information.

**Fluency** Although absolute agreement between judges was low,\(^6\) pairwise agreement in terms of Spearman rank correlation ($\rho$) is reasonable (average: .69, best: .91, worst: .56). For the subset of instances with multiple annotations, we used the data from the judge with the highest average pair-wise agreement ($\rho = .86$).

The fluency ratings are summarised in Figure 1. Judges ranked both monologues and dialogues for the GEN sample higher than for the CORPUS sample (possibly as a result of slightly greater length of the CORPUS fragments and some use of archaic language). However, the drop in fluency, see Figure 2, from monologue to dialogue is greater for GEN sample (average: .89 points on the rating scale) than the CORPUS sample (average: .33) (T-test $p < .05$), suggesting that there is scope for improving the generation algorithm.

---

\(^6\)For the four judges, we had an average pairwise $\kappa$ of .34 with the maximum and minimum values of .52 and .23, respectively.
Direct versus Complex rules  We examined the difference in fluency drop between direct and complex rules. Figure 3 shows that the drop in fluency for dialogues generated with complex rules is higher than for the dialogues generated using direct rules (T-test p < 0.05). This suggests that use of direct rules is more likely to result in high quality dialogue. This is encouraging, given that Stoyanchev and Piwek (2010a) report higher frequencies in professionally authored dialogues of dialogue acts (YNQ, Expl) that can be dealt with using direct verbalisation (in contrast with low frequency of, e.g., FactQ).

Figure 3: Decrease in Fluency Score from Monologue to Dialogue comparing Direct (24 samples) and Complex (14 samples) dialogue generation rules

5 Conclusions and Further Work

With information presentation in dialogue form being particularly suited for education and persuasion, the presented system is a step towards making information from text automatically available as dialogue. The system relies on discourse-to-dialogue structure rules that were automatically extracted from a parallel monologue/dialogue corpus. An evaluation against a benchmark sample from the human-written corpus shows that both accuracy and fluency of generated dialogues are not worse than that of human-written dialogues. However, drop in fluency between input monologue and output dialogue is slightly worse for generated dialogues than for the benchmark sample. We also established a difference in quality of output generated with complex versus direct discourse-to-dialogue rules, which can be exploited to improve overall output quality.

In future research, we aim to evaluate the accuracy and fluency of longer stretches of generated dialogue. Additionally, we are currently carrying out a task-related evaluation of monologue versus dialogue to determine the utility of each.

Acknowledgements

We would like to thank the three anonymous reviewers for their helpful comments and suggestions. We are also grateful to our colleagues in the Open University’s Natural Language Generation group for stimulating discussions and feedback. The research reported in this paper was carried out as part of the CODA research project (http://computing.open.ac.uk/coda/) which was funded by the UK’s Engineering and Physical Sciences Research Council under Grant EP/G020981/1.
