Bcl-2 functionally interacts with inositol 1,4,5-trisphosphate receptors to regulate calcium release from the ER in response to inositol 1,4,5-trisphosphate

Introduction

Inositol 1,4,5-trisphosphate (InsP$_3$) receptors (InsP$_3$Rs) are channels responsible for calcium release from the endoplasmic reticulum (ER). We show that the anti-apoptotic protein Bcl-2 (either wild type or selectively localized to the ER) significantly inhibited InsP$_3$Rs-mediated calcium release and elevation of cytosolic calcium in WEHI7.2 T cells. This inhibition was due to an effect of Bcl-2 at the level of InsP$_3$Rs because responses to both anti-CD3 antibody and a cell-permeant InsP$_3$ ester were decreased. Bcl-2 inhibited the extent of calcium release from the ER of permeabilized WEHI7.2 cells, even at saturating concentrations of InsP$_3$, without decreasing luminal calcium concentration. Furthermore, Bcl-2 reduced the open probability of purified InsP$_3$Rs reconstituted into lipid bilayers. Bcl-2 and InsP$_3$Rs were detected together in macromolecular complexes by coimmunoprecipitation and blue native gel electrophoresis. We suggest that this functional interaction of Bcl-2 with InsP$_3$Rs inhibits InsP$_3$R activation and thereby regulates InsP$_3$-induced calcium release from the ER.

Abbreviations used in this paper: BN-PAGE, blue native–PAGE; ECB, extracellular buffer; D-myo InsP$_3$, D-myo inositol 1,4,5-trisphosphate; HCB, intracellular buffer; IL-2, interleukin-2; InsP$_3$, inositol 1,4,5-trisphosphate; InsP$_3$R, InsP$_3$ receptor; TCR, T cell receptor; TG, thapsigargin; TMRE, tetramethylrhodamine ethyl ester.
Bcl-2 inhibits anti-CD3–induced calcium elevation

To investigate the effect of Bcl-2 on calcium homeostasis, the T cell receptor (TCR)–positive WEHI7.2 line was stably transfected with an expression vector encoding human Bcl-2 or empty control vector. Bcl-2 was not detected in nontransfected cells or in empty vector transfected control clones (Fig. 1 A; N1 and N2), but was readily detectable in Bcl-2–positive clones (Fig. 1 A; B1, B13, B17, and B27). Bcl-2 expression was monitored frequently by flow cytometry and only cultures with more than 85% of Bcl-2–positive cells were used in experiments. Bcl-2 expression conferred resistance to apoptosis induction by dexamethasone, staurosporine, and thapsigargin (TG; unpublished data). Substantial differences were not detected in the expression levels of InsP₃ Rs (Fig. 1 B), SERCA pumps (Fig. 1 C), or luminal calcium binding proteins (not depicted).

Antibody to the CD3 component of the TCR induced a calcium elevation in control WEHI7.2 cells that was inhibited in Bcl-2–transfected cells (Fig. 2 A). Bcl-2 expression also reduced both the number of cells responding to anti-CD3 antibody (Fig. 2 B) and the amplitude of calcium elevation in responding cells (Fig. 2 C). In addition, Bcl-2 expression appeared to increase the latency up to 2 min between the time when anti-CD3 antibody was added and when the elevation of cytosolic calcium was first detected. The inhibitory effect of Bcl-2 on anti-CD3–induced calcium elevation was confirmed by directly comparing multiple Bcl-2–negative and –positive clones (Fig. 3, A and C). Also, Bcl-2 selectively targeted for expression on the ER inhibited anti-CD3–induced calcium elevation (Fig. 3 E).

ER calcium levels are not affected by Bcl-2 expression

We investigated several possible mechanisms by which Bcl-2 expression could decrease agonist-induced calcium signals. First, we tested whether or not Bcl-2 expression affected ER calcium levels. This test was performed by two complementary approaches: (1) quantitation of the TG releasable calcium pool and (2) direct measurement of free luminal calcium concentration. TG inhibits SERCA pumps and causes a passive leak of calcium from ER lumen into cytoplasm.

Figure 1. Characterization of Bcl-2–positive and –negative clones. Western blot of cell lysates from nontransfected (wild type, WT) WEHI7.2 cells, control clones transfected with empty vector (N1 and N2), and clones stably expressing full-length Bcl-2 (B1, B13, B17, and B27). (A) The blot was probed with anti–hBcl-2 (human Bcl-2) antibody, then reprobed with anti-actin antibody to control for loading. (B) Blots were probed with antibodies to InsP₃ Rs I and III. (C) Blots were probed with antibodies to SERCA3, then reprobed with anti-actin antibody to control for loading.
TG-induced calcium elevation is an indirect measure of ER calcium content. We found no difference in the magnitude of the TG releasable calcium pool (Fig. 3, B, D, and F). Therefore, absence of an effect of Bcl-2 on TG-induced calcium elevation suggests that the inhibitory effect of Bcl-2 on anti-CD3-induced calcium elevation is not secondary to a Bcl-2-imposed decrease in ER luminal calcium concentration.

Luminal calcium concentration was measured directly using the low affinity calcium-sensitive dye Fura-2FF AM. Optimal conditions for loading Fura-2FF AM into the ER were determined in preliminary experiments. The organelle distribution of Fura-2FF fluorescence was in a reticular pattern distinct from the punctate mitochondrial pattern detected with the potentiometric dye tetramethylrhodamine ethyl ester (TMRE; Fig. 4 A). To quantify the relative amount of Fura-2FF localized to the ER lumen, the plasma membrane was permeabilized with digitonin and cells were perfused with intracellular buffer (ICB) supplemented with an ATP-regenerating system, 10 μM InsP₃, and 100 μM MnCl₂ (Fig. 4 B). The initial decrease in the emission intensity at both 340 and 380 nm excitation (at ~80 s) signifies the point at which the plasma membrane is permeabilized. The subsequent decrease in 340 and 380 nm emission (at ~190 s) is due to InsP₃-induced opening of InsP₃Rs on the ER, allowing MnCl₂ to enter the ER lumen. Fura-2FF has high affinity for MnCl₂, which in turn quenches the dye. In multiple experiments, more than 90% of the fluorescence remaining after digitonin permeabilization was quenched by perfusing cells with 10 μM InsP₃ and 100 μM MnCl₂. Using this assay system, ER luminal calcium concentration was

Figure 2. Inhibition of CD3/TCR-mediated calcium elevation by Bcl-2. Cytosolic calcium concentration was measured by single cell calcium imaging using the calcium indicator Fura-2 AM in the presence of 1.3 mM extracellular calcium. (A) Representative calcium traces comparing Bcl-2–negative (N1) and –positive (B27) clones. (B) The number of cells responding or failing to respond with a significant increase in cytoplasmic calcium concentration twofold above baseline after exposure to anti-CD3 antibody. (C) Peak calcium elevation induced by anti-CD3. Only cells responding to anti-CD3 antibody are included in the analysis. Symbols represent mean ± SEM and summarize data from a total of 161 N1 cells (five separate experiments) and 181 B27 cells (six separate experiments). Statistical analysis was performed with the Mann-Whitney U Test and confirmed with the Wilcoxon Rank Sum Test.

Figure 3. Bcl-2 inhibits anti-CD3–induced calcium elevation, but not TG-induced calcium elevation. Cytosolic calcium elevation induced by anti-CD3 antibody and by TG was measured in parallel in multiple Bcl-2–positive and –negative clones described in Fig. 1. Cells were incubated in ECB containing 1.3 mM calcium until the beginning of recordings when EGTA was added to chelate extracellular calcium. Fluorometry tracings show the transient elevation of cytosolic calcium induced by anti-CD3 antibody (A) or by 100 nM TG (B). Histograms summarize the peak cytosolic calcium elevation induced by anti-CD3 antibody (C) or 100 nM TG (D) in multiple experiments (mean ± SEM). E and F summarize multiple experiments (mean ± SEM) in which peak calcium elevation induced by anti-CD3 (E) and by 100 nM TG (F) was measured in WEHI7.2 cells stably expressing Flag-tagged wild-type Bcl-2 and Flag-tagged ER-targeted Bcl-2 or control expression vector (Neo).
compared in Bcl-2–negative and –positive clones. A typical continuous single cell tracing is shown in Fig. 4 C. Cells were initially perfused with extracellular buffer (ECB) and then with ICB supplemented with an ATP regenerating system and digitonin. The 340:380 fluorescence emission ratio increased dramatically when cells were permeabilized by digitonin. Cells were then perfused with ICB containing 10 μM InsP₃ and 100 μM MnCl₂. Mn²⁺ enters the ER and quenches luminal Fura-2FF after opening of InsP₃Rs by InsP₃. (C) Typical single cell traces monitoring the ratio of fluorescence at 340 and 380 nm excitation. The 340:380 ratio increases rapidly when cells are permeabilized with digitonin. The 340:380 ratio gradually reaches steady-state levels. (D) Summary of luminal ER calcium concentration based on steady-state 340:380 ratios after cell permeabilization with digitonin. Measurements were performed in six experiments constituting parallel comparisons of 59 Neo1 control cells versus 50 B27 cells, and in 13 experiments constituting parallel comparisons of 180 Neo2 control cells versus 85 B17 cells. Symbols represent mean ± SEM. Statistical analysis was performed with the Mann-Whitney U Test and confirmed with the Wilcoxon Rank Sum Test.

Thus, the inhibition of anti-CD3–induced calcium elevation by Bcl-2 is due either to Bcl-2–mediated interference with the signal transduction pathway that mediates this response or to a direct effect of Bcl-2 on InsP₃R function.

**Bcl-2 targets the InsP₃R to inhibit calcium release**

To exclude the first possibility, the signal transduction pathway mediating the response to anti-CD3 antibody was bypassed by measuring cytoplasmic calcium elevation after addition of a cell-permeant InsP₃ ester, D-myo InsP₃ hexakisbutyryloxyethyl ester (D-myo InsP₃BM), to intact Bcl-2–positive and –negative cells. After a brief delay required for de-esterification, D-myo InsP₃BM induced an elevation in cytosolic calcium that had a shorter latency period, a more rapid rate of increase, and a higher peak amplitude in Bcl-2–negative cells compared with Bcl-2–positive cells (Fig. 5). These findings indicated that Bcl-2 acts at
Bcl-2 regulates InsP3-induced calcium release

Chen et al. 197

the level of the ER to inhibit anti-CD3–induced calcium elevation, rather than interfering with upstream components of the signal transduction pathway initiated by TCR activation.

To examine further if Bcl-2 was acting at the level of InsP3, Rs, the affinity of InsP3, Rs for InsP3 was measured in microsomes isolated from Bcl-2–positive and –negative cells using a competitive binding assay. The $K_d$ for radiolabeled InsP3 binding was consistently higher in Bcl-2–positive microsomes than in Bcl-2–negative microsomes (7.0 ± 1.3 nM vs. 4.8 ± 1.1 nM; P < 0.001), indicating that Bcl-2 decreases InsP3, R binding affinity. To determine if decreased InsP3 binding affinity fully explains the inhibitory effect of Bcl-2 on InsP3, induced calcium elevation, the relationship between InsP3 concentration and calcium release from the ER was investigated. For this purpose, ER luminal calcium was continuously monitored with the low affinity calcium indicator Fura-2FF, before and after adding InsP3 to cells in which the plasma membrane had been permeabilized by digitonin. In typical calcium tracings, increasing concentrations of InsP3 induced a stepwise decrease in Fura-2FF ratio, reflecting a stepwise decline in luminal calcium due to InsP3-induced release of calcium into the cytoplasm (Fig. 6 A). This finding was highly reproducible as shown in the InsP3 dose response analysis and indicates that Bcl-2 inhibits the extent of InsP3–induced calcium release from the ER even at saturating InsP3 concentrations (Fig. 6 B). In contrast, the extent of calcium release induced by TG was similar in Bcl-2–positive and –negative cells (Fig. 6 C). These findings indicate that Bcl-2 inhibits InsP3–induced calcium release, even at saturating InsP3 concentrations well above the $K_d$ for InsP3 binding. Thus, an alteration in InsP3 binding affinity does not fully explain the inhibition of InsP3–induced calcium release by Bcl-2. Nevertheless, these findings further
suggest that Bcl-2 regulates cellular calcium signaling at the level of the InsP₃Rs.

**Bcl-2 inhibits InsP₃R channel opening in vitro**

To determine if Bcl-2 regulates InsP₃R channel activity, the effect of purified full-length Bcl-2 protein on single type I InsP₃R channels was studied after addition of ~0.1 μM purified full-length Bcl-2 to the solution bathing the cytoplasmic face of the channel. (A) Representative single channel traces showing the level of activity of a channel under control conditions (top trace; cis/trans 220 mM CsCH₃SO₃/20 mM CsCH₃SO₃, pH 7.4) in the presence of 2 μM InsP₃. The holding potential was 0 mV. Channel openings are seen as upward current deflections. The bottom trace shows the same InsP₃R channel after addition of Bcl-2 to the cis compartment (cytoplasmic side of channel). Bcl-2 significantly reduces the open probability. The bar at the left indicates the zero current level (closed state). (B) All-points amplitude histogram of the experiment shown in A. The effect on open probability is demonstrated by a reduction of the peak representing the open level.
Bcl-2 regulates InsP₃-induced calcium release

Chen et al. 199250/50 mM KCl; unpublished data). In this case, the total recording time considered in the analysis was much longer (120 s) for each condition. Addition of ~0.1 μM Bcl-2 to the cytoplasmic face of the InsP₃R reduced the channel open probability by 2.92-fold. Potassium or cesium are commonly used instead of calcium because conductance of the channel for monovalent cations is much higher than that for divalent cations, improving the resolution (signal to noise ratio) of single channel currents without significantly changing gating properties. In summary, these results demonstrate an inhibitory interaction between Bcl-2 and InsP₃Rs in vitro.

Bcl-2 and InsP₃Rs form a macromolecular complex in WEHI7.2 cells

To determine if Bcl-2 associates with InsP₃Rs in vivo, ER membranes were isolated from Bcl-2–expressing WEHI7.2 cells (clone 17) and subjected to blue native–PAGE (BN-PAGE), a technique in which protein complexes are separated in the first dimension on nondenaturing gels and protein complexes are then analyzed by SDS-PAGE/Western blotting in the second dimension (Schagger et al., 1994). Multiple high molecular mass complexes were resolved in first dimension gels (Fig. 8 B). The four largest complexes were cut from the gel and subjected to SDS-PAGE/Western blotting (Fig. 8 C). The findings indicate that at least a portion of Bcl-2 is located together with InsP₃Rs in the largest complex. Bcl-2 was also detected in the smaller complexes analyzed, suggesting either that some of the Bcl-2 had dissociated from the InsP₃R complexes during preparation or that not all of the Bcl-2 is associated with InsP₃Rs.

The potential interaction of Bcl-2 and InsP₃Rs was further analyzed by coimmunoprecipitation (Fig. 9). InsP₃Rs were immunoprecipitated from Neo control cells (clone N1) and Bcl-2–expressing cells (clone B17), and immunoprecipitates were analyzed by Western blotting with an antibody specific for Bcl-2 (Fig. 9 A). The results indicate that Bcl-2 coimmunoprecipitates with InsP₃Rs. Bcl-2 coimmunoprecipitation with InsP₃Rs was detected using antibodies to each of the three InsP₃R subtypes (Fig. 9 B). In the reciprocal experiment, Bcl-2 was immunoprecipitated and InsP₃Rs were detected as coimmunoprecitating proteins by Western blotting, confirming the interaction between Bcl-2 and InsP₃Rs (Fig. 9 C). To control for the specificity of interaction between Bcl-2 and InsP₃Rs, immunoprecipitates were also analyzed by Western blotting using an antibody to SERCA3 (Fig. 9 D). This ER membrane protein did not coimmunoprecipitate with either Bcl-2 or InsP₃Rs. Because the associations described in Fig. 9 (A–C) were shown in cells overexpressing Bcl-2, we next examined if similar interactions occurred in cells that endogenously expressed Bcl-2. For this purpose, we took advantage of another T cell line, S49.A2, immunoprecipitated from Neo control cells (clone N1) and Bcl-2–expressing cells (clone B17), and immunoprecipitates were analyzed by Western blotting using an antibody specific for Bcl-2 (Fig. 9 A). The results indicate that Bcl-2 coimmunoprecipitates with InsP₃Rs. Bcl-2 coimmunoprecipitation with InsP₃Rs was detected using antibodies to each of the three InsP₃R subtypes (Fig. 9 B). In the reciprocal experiment, Bcl-2 was immunoprecipitated and InsP₃Rs were detected as coimmunoprecipitating proteins by Western blotting, confirming the interaction between Bcl-2 and InsP₃Rs (Fig. 9 C). To control for the specificity of interaction between Bcl-2 and InsP₃Rs, immunoprecipitates were also analyzed by Western blotting using an antibody to SERCA3 (Fig. 9 D). This ER membrane protein did not coimmunoprecipitate with either Bcl-2 or InsP₃Rs. Because the associations described in Fig. 9 (A–C) were shown in cells overexpressing Bcl-2, we next examined if similar interactions occurred in cells that endogenously expressed Bcl-2. For this purpose, we took advantage of another T cell line, S49.A2,
which has been demonstrated to express Bcl-2 (Wang et al., 2003). Coimmunoprecipitation of endogenous Bcl-2 with InsP₃Rs, using either anti–Bcl-2 or anti–InsP₃R antibody, was detected in these cells (Fig. 9 E). SERCA3 did not coimmunoprecipitate with either endogenous Bcl-2 or InsP₃Rs (Fig. 9 F). In summary, the findings of coimmunoprecipitation experiments suggest that Bcl-2 forms a complex with InsP₃Rs.

Discussion

Here we report that Bcl-2 inhibits InsP₃-induced calcium elevation in the WEHI7.2 T cell line. The focus has been on understanding the mechanism by which Bcl-2 inhibits anti-CD3–induced calcium elevation. The findings of a systematic series of experiments all point to a regulatory effect of Bcl-2 on InsP₃R function. First, the observation that Bcl-2 inhibits anti-CD3–induced calcium elevation was confirmed in multiple Bcl-2–expressing clones of the WEHI7.2 line by both fluorometric and digital imaging methods of calcium measurement. Second, an inhibitory effect of Bcl-2 on ER calcium release was detected when the signal transduction pathway mediating anti-CD3–induced InsP₃ synthesis was bypassed by adding a cell-permeant InsP₃ ester to cells or by adding InsP₃ to digitonin-permeabilized cells. Third, anti-CD3–induced calcium elevation was inhibited not only by wild-type Bcl-2, which localizes to both the ER and mitochondria, but also by Bcl-2 selectively targeted to the ER membrane. These findings indicate that the action of Bcl-2 resides at the level of the ER, rather than in the upstream signal transduction pathway that mediates InsP₃ synthesis. Fourth, a series of control experiments indicated that inhibition of InsP₃-induced calcium release by Bcl-2 was not due to decreased luminal calcium concentration, decreased InsP₃R levels, or altered expression of luminal calcium binding proteins. Fifth, Bcl-2 inhibited the extent of InsP₃-induced calcium release even at saturating InsP₃ concentrations, indicating that the major action of Bcl-2 is not to decrease the affinity of InsP₃Rs for InsP₃, but to decrease InsP₃R channel opening even under conditions of maximal stimulation. Although the complete mechanism is yet to be determined, based on coimmunoprecipitation and BN-PAGE experiments it appears that Bcl-2 coexists in a macromolecular complex with InsP₃Rs, resulting in an inhibition of InsP₃-induced calcium release. This concept is further supported by in vitro evidence that purified Bcl-2 inhibited the frequency of InsP₃ channel opening when added to InsP₃Rs integrated into planar lipid bilayers.

Although an inhibitory action of Bcl-2 on InsP₃-mediated calcium release has not been reported previously, an inhibitory effect of Bcl-2 on calcium-mediated signaling pathways has been reported, including the induction of the transcription factor c-fos (Qi et al., 1997). Significantly, Linette et al. (1996) demonstrated that Bcl-2 inhibits anti-CD3/TCR–mediated activation of NFATc and induction of interleukin-2 (IL-2) expression, thereby inhibiting cell cycle entry by delaying Go/G₁ transition into S phase and also inhibiting TCR activation-mediated apoptosis. Active NFATc is generated by calcineurin, which binds to and dephosphorylates NFATc in the cytoplasm, permitting NFATc to enter the nucleus. It has been suggested that Bcl-2 inhibits NFATc activation by sequestering calcineurin to intracellular membranes (Shibasaki et al., 1997). Our findings suggest that Bcl-2 may inhibit calcineurin activation by inhibiting InsP₃-mediated calcium release from the ER. In T cells, calcium/calcineurin-mediated activation of NFATc increases IL-2 expression, which in turn stimulates dual pathways, one leading to cell death and the other leading to cell survival. IL-2 induces cell death via Stat2-mediated induction of the death receptor ligand Fas, whereas IL-2 promotes cell survival via Akt-mediated induction of Bcl-2 expression (Parijs et al., 1999). The findings of the present paper raise the possibility that increased expression of Bcl-2 may form a feedback loop that dampens InsP₃-mediated calcium signals, thereby controlling T cell proliferation while maintaining cell survival. InsP₃Rs are known to associate with several factors that regulate InsP₃-gated channel activity (Mackrill, 1999; Rodrick and Bootman, 2003). This paper is the first to suggest that Bcl-2 may interact with InsP₃Rs and regulate their functional activity. Although the full functional significance of the inhibitory effect of Bcl-2 on InsP₃R channel activity is as yet unknown, this action of Bcl-2 may contribute to the established inhibitory effects of Bcl-2 on cell cycle entry and/or apoptosis induction. In view of the wide range of cellular functions mediated by InsP₃-induced calcium signals (Beridge et al., 2003), it will be interesting in future studies to determine if the function of Bcl-2 goes beyond that of regulating cell cycle entry and apoptosis.

Materials and methods

Reagents

TG, EGTA, digitonin, and other reagents were obtained from Sigma-Aldrich. D-myo-InsP₃ and L-myo-InsP₃ were obtained from Calbiochem. Fura-2 AM was obtained from Molecular Probes. Fura-2FF AM was obtained from Tef Labs. Hamster anti-mouse CD3ε epsilon chain mAb was obtained from BD Biosciences.

Cell culture and transfection procedures

WEHI7.2 and S49.A2 cells were cultured in DME supplemented with 10% serum, 1-glutamine, and nonessential amino acids. Human Bcl-2 cDNA from the pIB plasmid (American Type Culture Collection) was cloned into the pSFFV-Neo vector. Transfection and cloning were performed as described previously (Dieken and Miesfeld, 1992). Flag-tagged Bcl-2 was selectively localized to the ER by exchanging the COOH-terminal transmembrane sequence of Bcl-2 for the ER-targeting sequence of cytochrome b₅₃, as described previously (Wang et al., 2001). Bcl-2 expression was monitored by flow cytometry of fixed cells using anti-Bcl-2 antibody (BD Biosciences; 15131A) at a 1:500 dilution and Alexa Fluor 488 goat anti–hamster IgG (H+L) conjugate (Molecular Probes; A-21170) as the secondary antibody at a dilution of 1:500.

Calcium fluorometry

Cells (10 ml volume, 1 million per milliliter) were incubated with 1 μM Fura-2 AM for 45 min at 25°C in ECB (130 mM NaCl, 5 mM KCl, 1.5 mM CaCl₂, 25 mM Hepes, pH 7.5, 1 mg/ml BSA, and 5 mM glucose), after which they were pelleted and resuspended in ECB for an additional incubation at 25°C for 30 min to permit dye de-esterification. Fluorescence was continuously recorded at 37°C (alternating 340 and 380 nm excitation, 510 nm emission) in a fluorometer (Photon Technology Inc.). EGTA (final concentration 10 mM) was added to chelate extracellular calcium immediately before adding 100 mM TG, anti-CD3 antibody (BD Biosciences; 1:150 dilution), or 25 mM D-myo InsP₃ (BM). In experiments using D-myo InsP₃ (BM), the volume of cell suspensions was scaled down to 250 μl in a 300 μl cuvette. All measurements were performed in triplicate. Rₘₐₓ and Rₘᵢₙ values were determined in each experiment by cell permeabilization with digitonin, followed by sequential addition of calcium and EGTA/
Tris. Calcium concentration was calculated, based on the published Kd of Fura-2 of 220 nM, by the equation of Grynkiewicz et al. (1985) using Felix Software (Photon Technologies Inc.).

**Calcium imaging**

Cells adhered to poly-l-lysine-coated coverslips (15 mm) were loaded with 1 μM Fura-2 AM (Molecular Probes) as described in Calcium Fluorometry. Coverslips were placed in a recording/perfusion chamber (model RC-25F; Warner Instruments) mounted on the stage of an inverted microscope (model Diaphot; Nikon) equipped with a 20x Fluor objective. Excitation light was alternated between 340 and 380 nm by a filter wheel (Sutter Instrument Co.) and emitted light was filtered at >510 nm and collected with an intensified charge-coupled device camera (model Ultraview; PerkinElmer). The video signal was digitized using UltraView software (PerkinElmer) and subsequently processed using Microsoft Excel. Cells were perfused with ECB at 25°C and stock solutions of both anti-CD3 antibody (1:40 dilution) and 22 μM D-myo InsP3BM were diluted in ECB immediately before addition to the perfusion chamber. To determine Rmin, cells were perfused with ECB deficient in calcium and supplemented with 4 mM EGTA and 10 μM D-myo InsP3BM, Rmax was obtained by perfusing cells with ECB supplemented with 4 mM CaCl2 and 10 μM D-myo InsP3BM. Calcium concentration was calculated as described in Calcium Fluorometry.

**ER calcium measurement**

Luminal calcium measurement was modified after that of Hofer (1999). Cells, adhered to poly-l-lysine-coated coverslips were incubated with 1 μM Fura-2FF AM for 30 min at 37°C in ECB, after which the buffer was replaced with fresh ECB and the incubation continued for 45 min at 25°C to permit de-esterification. Cell imaging was performed as described in Calcium imaging. Cells were initially perfused with ECB at 25°C, and then with ICB (125 mM KCl, 25 mM NaCl, 10 mM Hepes, 0.5 mM Na2ATP, 200 μM CaCl2, and 500 μM EGTA, pHi 7.25), supplemented with an ATP-regenerating system consisting of 10 μg/ml creatine phosphokinas-type A and 10 μM phosphocreatine. As soon as cells were permeabilized, the perfusion buffer was switched to ICB plus ATP-regenerating system. After the fluorescence ratio reached steady-state, the cells were perfused with the same buffer supplemented with D-myo-InsP3, at concentrations given in the text and accompanying figures. Stock solutions of D-myo-InsP3, and L-myo-InsP3, were prepared at a concentration of 3 mM in calcium-free water and stored at −20°C until use. After cell permeabilization with digitonin, the proportion of Fura-2FF located in the ER was determined by quenching luminal dye by perfusing with 10 μM D-myo-InsP3 in ECB supplemented with 100 μM MnCl2. To determine Rn, permeabilized cells were perfused with ECB deficient in calcium and supplemented with 4 mM EGTA and 10 μM D-myo InsP3BM. Rn was obtained by perfusing permeabilized cells with ECB supplemented with 4 mM CaCl2.

The InsP3, dose response relationship was determined by sequential addition of D-myo-InsP3, to digitonin-permeabilized cells while continuously monitoring the Fura-2FF 340:380 ratio. The InsP3-mediated change in the 340:380 ratio was plotted as a function of InsP3 concentration by nonlinear least squares best fit of the data to the Langmuir isotherm equation using Origin 6.0 (Microcal).

**Immunoprecipitation**

Confocal Z-series stacks of TMRE-loaded (0.1 μM, 10 min) cells were acquired after permeabilization with digitonin in ICB at RT using an UltraView LCI (PerkinElmer) with a microscope (model TE300; Nikon), ×100/1.3 objective (Nikon), and Orca ER camera (Hamamatsu) at excitation 568 nm, emission 600 ± 40 nm. The laser intensity was kept at a minimum to prevent irradiation-induced mitochondrial damage. Image acquisition was by UltraView software (PerkinElmer). Nonconfocal Z-series stacks of Fura-2FF loaded cells were obtained after permeabilization with digitonin in ICB at RT using an UltraView LCI with a microscope, ×100/1.3 objective, epifluorescence arc-lamp as a light source, excitation 330–380 nm, dichroic 380LP, emission 470LP, and Orca ER camera. Subsequent image restoration was achieved with the deconvolution software AutoDeblur (Autoquant).

**Western blotting**

Cell lysates containing 40–60 μg of protein were separated by SDS-PAGE (15% for Bcl-2 and 4–15% linear gradient for InsP3Rs) followed by electroblotting on a nitrocellulose membrane-PVDF. The following antibodies and their respective dilutions were used: anti–human Bcl-2 (BD Biosciences; 15131A, 1:2000), anti–mouse Bcl-2 (BD Biosciences; 554218, 1:1000), anti-actin (Santa Cruz Biotechnology, Inc.; sc-8432, 1:1000), anti-InsP3R Type I (Calbiochem; 407144, 1:2000), anti-InsP3R Type II (Chemicon; AB3000, 1:100), anti-InsP3R Type III (BD Biosciences; 610312, 1:2000), and anti-SERCA3 ATPase (Affinity Bio- Reagents, Inc.; PA1-910, 1:500).

**BN-PAGE**

ER membranes were isolated from WEHI7.2 cells as described previously (Kornke et al., 1993). In brief, cells (1–10 × 106) were washed twice with ice-cold PBS (Invitrogen), pH 7.2, and resuspended in 1.5 ml of homogenization buffer (20 mM Hepes, pH 7.4, 2.5 mM EDTA, 250 mM sucrose, and protease inhibitor cocktail. After homogenization for 15–25 strokes with a Dounce homogenizer, samples were centrifuged at 3,000 g for 15 min at 4°C and 1 ml of supernatant was layered onto an 11-mL sucrose gradient (0.75 to 1.9 M sucrose in 20 mM Hepes, pH 7.4, and 2.5 mM EDTA) and centrifuged for 1 h at 110,000 g. Fractions of 0.8 ml were collected from the gradient and the distribution of ER and mitochondria was determined by Western blotting. Calnexin (anti-calnexin antibody, SPA-8600; StressGen Biotechnologies) and Cox IV (anti IV COX, A-6430; Molecular Probes) were used as markers of ER and mitochondria, respectively. Fractions containing purified ER membranes were pooled and mixed with three volumes of 20 mM Hepes, pH 7.4. The sample was centrifuged at 105,000 g for 1.5 h at 4°C and the resulting membrane pellet was used for BN-PAGE, performed as described previously (Schagger et al., 1994). The ER membrane was solubilized with 750 mM 6-aminocaproic acid, 50 mM BisTris, pH 7.0, and 1% deoxy maltoside (5 μg total protein per microliter) and centrifuged at 100,000 g for 15 min at 4°C. Before starting BN-PAGE, Coomassie blue was added to the resulting supernatant to 0.25%. 100 μg of protein was added to each well of 4–10% linear gradient BN-PAGE. Single bands were excised from the blue native gel and applied to a 4–20% linear gradient SDS-PAGE with sample buffer, followed by Western blotting. Sizes of molecular complexes were estimated using a high molecular mass calibration kit for native electrophoresis (17–0445-01; Amersham Biosciences). After completion of electrophoresis, gels were subjected to Western blotting using antibodies to InsP3Rs and human Bcl-2 as described above.

**Innopolishing**

10× cells were washed twice with PBS and incubated on ice 30 min with 1 ml lysis buffer (50 mM Tris–HCl, pH 7.5, 100 mM NaCl, 2 mM EDTA, 1% CHAPS wt/vol, 50 mM NaF, 200 mM acetic acid, 1 mM Na2VO4, and protease inhibitor cocktail [Complete Mini; Roche Applied Science]). Cell lysates were centrifuged at 20,000 g for 15 min at 4°C. The resulting supernatant was rotated with 100 μl of 50% protein A or protein G agarose beads at 4°C for 2 h. After removing the beads, the supernatant was incubated with one of the following antibodies: anti–human Bcl-2 (hamster 1:200; anti–mouse Bcl-2, 1:150; anti–InsP3R antibody, anti– InsP3R Type I, 1:200; or antibody recognizing all three subtypes [Calbiochem; 407143]) overnight at 4°C, followed by rotation with 50 μl protein A or G agarose for 2 h at 4°C. Nonspecific control antibodies used were rabbit serum (1:200 dilution; Life Technologies) and hamster IgG (5 μg/ml; BD Biosciences). The beads were washed four times with lysis buffer and boiled for 5 min in 50 μl sample buffer. The eluted proteins were resolved by SDS-PAGE and analyzed by Western blotting.

**InsP3, binding**

Specific binding of radiolabeled InsP3 to microsomes was measured as described previously (Riley et al., 2002). Microsomes (50 μg) were added in duplicate to 100 μl binding buffer (2 nM 3H-InsP3 [Dupont NET-911], 2 mM Tris, pH 9.0, 1 mM EDTA, and 1 mg/ml albumin, with or without a range of concentrations of unlabeled InsP3) and incubated on ice for 20 min. The mixture was centrifuged for 15 min at 20,000 g at 4°C. Pellets were solubilized in 100 μl water and added to 10 ml ACS scintillation cocktail (Amersham Biosciences) and their activity was determined by liquid scintillation counting. Non-specific binding was determined using an excess of unlabeled InsP3. The Kd was calculated by Scatchard analysis.

**Planar lipid bilayer analysis of InsP3R channel activity**

Full-length human Bcl-2 was purified from Escherichia coli M-15 (pRep4) cells transformed with a pProex-1H-bcl-2 using methods described previously (Lam et al., 1998). Type I InsP3Rs were purified from microsomes isolated from COS-1 cells transfected with pInsP3R-RT-D1-ALT plasmid as described previously (Mignery et al., 1989, 1990). Gradient fractions containing InsP3R protein were then identified by immunoblotting with Type 1 receptor antibody and reconstituted into proteoliposomes as previously described (Mignery et al., 1992; Perez et al., 1997). Planar lipid bilayers were formed across a 150-μm diameter aperture in the wall of a Delrin partition as described previously (Perez et al., 1997). Proteolipo-
some were added to the solution on one side of the bilayer (defined as the cis-chamber). The other side was defined as the trans-chamber. Standard solutions contained 220 mM CsCH₃SO₃ cis (20 mM trans), 20 mM Hepes, pH 7.4, and 1 mM EGTA ([Ca²⁺]free = 250 nM). A custom current/voltage conversion amplifier was used to optimize single-channel recording. Acquisition software (pClamp; Axon Instruments, Inc.), an IBM compatible 486 computer, and a 12-bit A/D-D/A converter (Axon Instruments, Inc.) were used. Single channel data were digitized at 5–10 KHz and filtered at 1 KHz. Channel sidedness was determined by InsP₃ sensitivity. The orientation of the channels studied was such that the InsP₃ sensitive side (i.e., cytoplasmic side) was in the cis compartment.

We thank George Dubyk, David Friel, Emiluds Reineks, Huiling He, Irma Lengu, Michael Malone, Anthony Berdis, Rod O’Conner, Steven Madison, and Anthony Holmes for advice and help with experiments. This work was supported by National Institutes of Health grants CA85804 and CA42755 (C.W. Distelhorst), by an International Union Against Cancer Yamagiva-Yoshida Memorial International Cancer Study grant (C.W. Distelhorst), and by Focusedt 1020927 and 7020927 (P. Velez). We also thank the Biotechnology and Biological Sciences Research Council and Human Frontier Science Programme (M.D. Boorman and H.L. Roderick) for financial support and the Engineering and Physical Sciences Research Council Mass Spectrometry Service for mass spectra.
