Introduction: Previous studies have identified isotopic hotspots in insoluble organic matter (IOM) from carbonaceous chondrites [e.g. 1,2]. The origins and formation mechanisms of these hotspots and the host IOM are a matter of ongoing debate. For example, it is not clear whether D and 15N enrichments in IOM formed within a common organic precursor in cold interstellar environments [3,4] or due to irradiation of organic material in the early Solar System [5,6]. It is also unclear what effect parent body processes would have had with regard to the alteration of meteoritic IOM [2]. In order to address these issues, more recent studies have attempted to make in-situ measurements of isotopic anomalies in IOM [e.g. 5]. In this study we present in-situ NanoSIMS isotopic analyses of material within a sample of the CM2 meteorite Cold Bokkeveld, comparing the distribution of hotspots and bulk H, C and N isotopic composition in the rims and interiors of altered chondrules.

Analytical Techniques: Back scattered electron (BSE) images were acquired with a FEI Quanta 200 3D microscope. These were then used to identify regions of interest within the sample (Fig. 1). C, N and H isotopic ratios were determined using a Cameca NanoSIMS 50L. Areas of 30×30 μm² were extensively pre-sputtered with the ion beam. Within these areas, 25×25 μm² regions were mapped with two different analytical setups: (1) 12C, 13C, 16O, 18O, 12C14N, 12C15N (4 pA probe, MRP >9000); and (2) 1H, 2H, 12C and 18O (10pA, MRP ≈ 4000). Data were reduced using the L’Image software (L. Nittler, Carnegie Institution of Washington). Post-NanoSIMS secondary electron (SE) images were acquired using a Zeiss Supra 55V.
analytical FEG SEM (Fig. 3a). All of the hotspots identified have sigma values of $\geq 4$ (as calculated in L’Image).

Results: A total of thirteen areas were analysed within three separate chondrules and their rims. An example of one such chondrule (CB6) is presented in Fig. 1. The bulk $\delta D$, $\delta^{15}N$ and $\delta^{13}C$ isotopic compositions of these areas are within the range reported for IOM in other carbonaceous chondrites (Fig. 2; [4]). H/C ratios within the Cold Bokkeveld areas are significantly higher than those of carbonaceous chondrite IOM, however, this is almost certainly due to the fact that these areas also include non-organic phyllosilicate material. The highest bulk $\delta D$, $\delta^{15}N$ and $\delta^{13}C$ values are observed within the rims of chondrules while the highest H/C ratios are observed in the chondrule interiors (Fig. 2).

D-enrichments. D-enrichments are identified in the rims of several chondrules (Fig. 2a). CB6_2 is an example of one area within which multiple D-enrichments were observed (Fig. 3c-d). These appear to correspond to depressions in the surface of the sample, as indicated in the SE image of CB6_2 (Fig. 3a). The D-enrichments also correlate to relatively C-rich areas of the sample (Fig. 3b).

$^{15}N$-enrichments. Less common than the D-enrichments are $^{12}C$ hotspots. However, one area within the rim of a chondrule (CB6_2) was found to contain several such hotspots (Fig. 2b). All of these correspond to relatively C-rich areas and two correspond to D-enrichments (Fig. 3c-f).

Discussion: The variation of bulk $\delta D$ values might reflect the incorporation of multiple materials into the chondrules [5], or could be due to post-accretionary remobilisation of D-rich IOM [2]. As with previous studies, our results indicate that $^{15}N$ and D hotspots are not always spatially correlated [1,3]. Based on the models of [3], nitriles are the most likely source of the $^{15}N$-enrichments that do not appear to be correlated with D hotspots. The combined $^{15}N$- and D-enrichments are most likely carried by amines. The putative association observed between isotopically anomalous IOM and chondrule rims and altered matrix may indicate the remobilisation of D-rich IOM post-accretion. More detailed characterisation of the mineralogical environment of D-rich grains may assist in establishing the extent to which equilibration of D has, or has not, occurred on parent bodies.

Acknowledgments: We thank Gordon Imlach from the electron microscope suite at the Open University for his assistance in the acquisition of SE images.
