Abstract

The MSRV (Multiple Sclerosis Associated Retro Virus) belongs to the human endogenous retrovirus HERV-W family. The envelope protein originating from the MSRV has been found in most patients with multiple sclerosis (MS). This protein (Env-ms) has pro-inflammatory properties for several types of immune cells and could therefore play a role in MS pathogenesis by promoting the leukocyte diapedesis observed in the central nervous system of patients. Our study aims to analyze the effects of Env-ms on the blood-brain barrier (BBB) at a molecular and functional level.

We demonstrate that the recombinant MSRV envelope is able to stimulate several inflammatory parameters in a human BBB in vitro model, the HCMC/D3 brain endothelial cell line. Indeed, Env-ms induces overexpression of ICAM-1, a major mediator of leukocyte adhesion to endothelial cells, in a dose-dependent manner as well as a strong dose-dependent production of the pro-inflammatory cytokines IL-6 and IL-8. Furthermore, using a silencing approach with siRNAs, we show that Env-ms is recognized via the TLR4 receptor, a pattern recognition receptor of innate immunity present on endothelial cells. We also show using functional assays, that treatment of brain endothelial cells with Env-ms significantly stimulated the adhesion and the transmigration of activated immune cells through a monolayer of endothelial cells.

These findings support the hypothesis that MSRV could be involved in the pathogenesis of MS disease or at least in maintenance of inflammatory conditions, thus fueling the auto-immune disorder. MSRV could also play a role in other chronic inflammatory diseases.
Introduction

Multiple sclerosis associated retroviral element (MSRV) is an enveloped retrovirus initially isolated from cell cultures from patients with multiple sclerosis (MS)(1). It is the first identified member of the human endogenous retrovirus W (HERV-W) family (2) which has infected the germline and, then has been transmitted to the offspring of their hosts in the course of primate evolution (3). Most of the integrated HERV-W display deletions or mutations in their open reading frames encoding functional proteins (4), thus preventing a complete expression. However, genetic elements of endogenous HERV are involved in genetic rearrangements (5) that can contribute to their genetic diversification and their occasional expression (3) which was reported in several diseases (see for review (6). To date, MSRV is the unique example of HERV-W expressed as viral particles. Pathological consequences of the exposure to MSRV were demonstrated in humanized SCID (Severe Combined Immuno-Deficiency) mice that responded by strong pro-inflammatory cytokines, such as TNF-α, leading to death by brain hemorrhages (7). Interestingly, pro-inflammatory and immunopathogenic effects of MSRV are achieved by its envelope protein (Env-ms) through the activation of TLR4 and its CD14 co-receptor (8,9). Of note, another member of the HERV-W family, integrated in the chromosome 7, possesses an expressed Env, called syncytin (Env-syn). However, Env-syn is found only in placenta playing an important role in the physiology of syncytiotrophoblast formation (2,10), whereas several studies demonstrate the presence of Env-ms in macrophages or microglial cells in active plaques of all MS brains (11,12). Moreover, Env-ms is found circulating in plasma from 73% of patients with MS and not in control donors (11). Interestingly, blood circulating Env-ms is also detected among some schizophrenic patients in correlation with their level of blood C-reactive protein showing a link between Env-ms and the systemic inflammation status of the patients (13). The precise action of MSRV in pathogenesis of MS remains still unclear. For instance, the relative chronology of the expression of Env-ms, i.e. in activated monocytes/macrophages of the brain versus in the circulating blood, is unknown and difficult, even impossible, to assess. Several lines of evidence suggest that the Env expression can originate from the trans-activation of endogenous sequences belonging to the HERV-W family by infectious co-factors such as Epstein-Barr virus which is often found in MS patients (11,14).

MS is an inflammatory demyelinating disease in which infiltrating lymphocytes and macrophages are observed in the perivascular space of central nervous system. The recruitment of immune cells to areas of demyelination is largely conditioned by blood brain barrier (BBB) integrity and by the inflammatory environment (see (15-18) for reviews). In the present study we measured the pro-inflammatory properties of two different envelope proteins originating either from MSRV (Env-ms) or its endogenous counterpart originating from an HERV-W element stably inserted into the chromosome 7 syncytin Env-syn). We assessed envelope protein effects on human brain endothelial cells.
(HCMEC/D3 cell line) reconstituting an in vitro blood brain barrier model (19), and on primary HUVECs. Furthermore, we investigated the mechanisms by which each envelope protein interacts with endothelial cells. We report that the recombinant MSRV envelope protein is able to trigger the secretion of several pro-inflammatory cytokines and the overexpression of ICAM-1, an adhesion molecule involved in key steps of leukocyte transendothelial migration, on both HCMEC/D3 and HUVECs. We also show that the pattern recognition receptor TLR4 is implicated in Env-ms recognition by HCMEC/D3 cells.
Materials and methods

Recombinant proteins

The recombinant Env-ms and Env-Syn proteins were obtained as previously described (8). Monoclonal antibodies GN-mAb01 and GN-mAb03, detecting both Env-ms and Env-Syn proteins and GN-mAb12, detecting gag protein, were obtained from Geneuro (Geneva, Switzerland).

Cells and culture conditions

HCMEC/D3 cells were obtained from P.O Couraud (Institut Cochin, Paris, France) and cultured as previously described (19). Briefly, cells were seeded onto collagen type 1 (Sigma-Aldrich, St Louis, MO, USA) coated flasks in supplemented EBM-2 medium (Lonza “bullet kit”, Basel, Switzerland) containing 2.5% FBS and growth factors, bFGF, VEGF, IGF, EGF at a final concentration 4X lower than recommended by the furnisher. Cells were obtained at passage 26 and cultured up to passage 36.

Primary cells HUVECs were cultured in M199 medium containing 20% heat-inactivated fetal bovine serum (FBS), ECGS (Endothelial Cells Growth Supplement, 50 μg/mL), heparin (100 μg/mL) and antibiotics. Cells were cultured up to passage 5 onto collagen type 1 (Sigma) coated flasks.

HL-60 cells, a human promyelocytic leukemia cell line was cultured in RPMI-1640 containing 10% FBS.

Cell stimulation

HCMEC/D3 or HUVECs were seeded onto collagen type 1 coated 24 well plates until reaching confluency. Media were then replaced with media containing recombinant proteins or stimulating cytokines for 16 hours. All conditions were tested in triplicate. After stimulation, cells were trypsinized and analyzed by flow cytometry for the expression of ICAM-1 and supernatants were collected, and frozen at -80°C before analysis by ELISA assays for the production of cytokines (IL-6, IL-8 and TNF-α detection kits purchased from PromoKine/Promcell, Heidelberg, Germany).

Adhesion and transmigration assays

For adhesion assays, HL-60 cells were cultured at a concentration of 2.10^5 cells/ml and activated with vitamin D3 (18.7 μg/ml) and indomethacin (Sigma-Aldrich, 10^-7 M) for 72 hours. HL-60 cells were detached with a scraper and labeled with calcein AM (Invitrogen Molecular Probes, Carlsbad, CA, USA) just before the experiment. Then 1.10^6 cells were left to adhere for 35 min onto a confluent HCMEC/D3 monolayer representing a surface of approximately 3.8 cm². After 3 washing steps with PBS, the remaining adherent cells were lysed with 1% SDS. For each condition, cell lysate is plotted in triplicate on a 96 well plate before fluorescence measurement. with a Victor 3 spectrophotometer (1420 multilabel counter, Perkin Elmer).
For transmigration assays, HCMC/D3 (2x10^4/well) were grown to confluency onto collagen-coated (100 µg/mL) porous polycarbonate membrane (Transwell, 8-µm pore size; 6.5 mm diameter, Costar, Cambridge, MA) for 3 to 4 days at 37°C and stimulated with TNFα (100U/mL) or 2 µg/mL of Env-ms for 18 hours prior to the assay. For inhibition experiments Env-ms (2µg/mL) was preincubated with monoclonal antibodies specific for Env-ms or gag protein (30 µg/mL, 30 min 4°C). Activated HL-60 cells (10^5 cells/well) were added to the upper compartment, A concentration of 2 x10^-8 M fMLP (Calbiochem-Novabiochem) was added in the lower compartment, to create a chemotactic gradient for PMN. After 1 hour at 37°C, migrated HL-60 cells were recovered from the bottom well, centrifuged, and quantified using a CyQUANT assay kit (Molecular Probes,Eugene, OR).

Immuno-staining for flow cytometry

After trypsinization, living cells were incubated for 1 hour at 4°C with anti ICAM-1 primary antibody (clone 2D5 produced locally as previously described (20). After centrifugation, pellets were resuspended in 50µl of RPMI 1640 containing the secondary antibody coupled with FITC (goat anti-mouse-FITC purchased from Jackson ImmunoResearch, Philadelphia, PA, USA) and left to incubate for 30min at 4°C. After centrifugation, cells were re-suspended in 500µl of RPMI 1640 + 10% FBS and fluorescence was measured with a FACSCAN flow cytometer (Beckton Dickinson, Le Pont-De-Claix, France). Results were analyzed using WinMDI software.

Immuno-staining for fluorescence microscopy

Cells were seeded onto LabTek chambers (Nunc, Rochester, NY, USA) until confluence and were then stimulated for 16 hours in the chambers. Cells were then washed twice with pre-warmed (37°C) PBS containing Ca^{++} and Mg^{++} and then fixed for 30min at room temperature with PBS Ca-Mg containing 2% paraformaldehyde and 2% sucrose. After fixation, we performed two quenching steps with PBS containing glycine 0.1M and NaN3 0.01% for 10min and a permeabilization step using PBS containing 0.2% saponin, 2% BSA, for 20min at room temperature. Staining was performed using either the anti-ICAM-1 primary antibody clone 2D5 with a secondary goat anti-mouse antibody coupled to TRITC (Jackson ImmunoResearch); anti-TLR4 (Santa Cruz, Santa Cruz, CA, USA) with a secondary goat anti-rabbit antibody coupled to Alexa 488; or the anti golgin 97 (Invitrogen) with a secondary goat anti-mouse antibody coupled with Alexa 555. Nuclei were labeled with Hoescht 33342. Cells were observed with an epi-fluorescence microscope (Carl Zeiss AxiolImager) with the pseudo-confocal module APOTOME. Images were analysed with ImageJ software (ImageJ, NIH, USA). For colocalization experiments, the Pearson’s correlation coefficient (Rr) and the Mander’s overlap coefficient (R) were calculated using the ImageJ colocalization plugin after background subtraction.
**Western blotting**

After reaching confluence, HCMEC/D3 cells were trypsinized and lysed for 30 min on ice with a Tris-HCl 50mM, pH 7.5, NaCl 150 mM buffer containing 1% NP40 or 0.1% SDS (as mentioned in each case) and a protease inhibitor cocktail (Sigma Aldrich). Whole cell extracts were submitted to SDS-PAGE (10% acrylamide gels), blotted onto polyvinylidene difluoride membranes and stained with a rabbit polyclonal primary antibody raised against TLR4 (Santa Cruz) or actin (Sigma Aldrich) and a secondary goat anti-rabbit antibody coupled with peroxidase (Invitrogen). Bands were quantified with BioRad Image Lab software.

**Treatment with peptide N-glycosidase (PNGase)**

Before analysis by western blotting, some extracts were treated by PNGase using a deglycosylation kit (Sigma, GlycoProfile II, Enzymatic In-solution N-Deglycosylation kit). Extracts were treated according to the furnishers’s recommendations but omitting the denaturation step before adding the PNGase to avoid precipitation of the proteins. Briefly, 50µg of extracts were treated with 2.5 units of PNGase or water as a negative control for 2 hours at 37°C, then immediately analyzed by western blotting.

**Small interfering RNA (siRNA) transfections**

SiRNA targeting TLR4 were transfected according to the manufacturer recommendations (Invitrogen). Briefly, we transfected the cells with a set of 3 siRNAs targeting TLR4 or with a negative control at a final concentration of 20nM (Stealth RNAi all provided by Invitrogen) using Lipofectamine RNAiMAX (Invitrogen) when cells reached 30% confluency. Cells were re-transfected 48 hours later under the same conditions. Forty-eight hours later, the transfected and control cells were treated with Env-ms or LPS and then analyzed.

**Statistics**

All results are expressed as mean ± SE. Data were analyzed using R statistical software; two-sided Student t test was used. Differences between conditions were considered significant at \( p < 0.05 \).
Results

Effects of Env-ms on HCMEC/D3 brain endothelial cells

First, we analyzed the effect of Env-ms on confluent monolayers of HCMEC/D3 cells. We observed by fluorescence microscopy an increase in expression of ICAM-1 adhesion molecules (Fig. 1A). In order to quantify ICAM-1 expression, cells were analyzed by flow cytometry for surface expression of ICAM-1 after incubation with TNF-α, which is known to activate endothelial cells, or with Env-ms; both treatments induced a strong ICAM-1 expression (Fig. 1B). The induction of ICAM-1 expression was specific for Env-ms, since treatment with Env-syn had no significant effect and was dose-dependent on the ENv-ms concentration (Fig. 1C). To further confirm the specificity of Env-ms proinflammatory properties, we pre-incubated Env-ms with monoclonal antibodies recognizing either Env-ms, or the gag protein of HERV as a negative control, before treating HCMEC/D3 cells. After overnight incubation with the treated Env-ms, ICAM-1 surface expression by HCMED/D3 cells was measured by flow cytometry as detailed above. Anti Env-ms antibodies blocked about 40% of Env-ms induced ICAM-1 expression as compared to the irrelevant anti-gag antibodies (Fig. 1D). We performed a complementary control to ensure that there is no LPS contamination in the recombinant envelope protein. For that purpose, we used polymyxin B (PB) antibiotic that can neutralize LPS activity. LPS or Env-ms were pretreated or not with PB and then incubated overnight with HCMEC/D3 cells. The pre-treatment with PB almost completely abolished the LPS induced ICAM-1 increased expression but had no effect on Env-ms induced ICAM-1 expression, indicating that Env-ms pro-inflammatory activity was not caused by LPS contamination (Fig. 1E).

We investigated the effects of Env-ms at a functional level by measuring the adhesion between activated immune cells and a monolayer of HCMEC/D3 cells. For that purpose, we used activated calcein labeled HL-60 cells adhering to the HCMEC/D3 monolayer. After several washing steps and lysis of all remaining adherent cells, we quantitated adherence of HL-60 cells by fluorescence readings. We observed an increase of adherent HL-60 cells when HCMEC D/3 cells had previously been treated with Env-ms (Fig. 1F). This increase was even stronger than the positive control with LPS treatment, but this was not statistically significant. These results are consistent with our observations (Fig 1A and 1B) of ICAM-1 increased expression following Env-ms treatment, since ICAM-1 is a major mediator of the adhesion between activated immune cells and endothelial cells ((20,21), see (22) for review).

Adhesion of leukocytes to the endothelium can be followed by leukocyte transendothelial migration. As shown in Fig 1G, Env-ms was able to stimulate transendothelial migration of HL60 cells; this increased transmigration was inhibited (by 80%) when Env-ms was pre-incubated with a specific
monoclonal antibody (GN-mAb03), while an antibody specific for Gag protein was devoid of any inhibitory effect.

Recombinant Env-ms induced a strong and dose dependent production of IL-6 (Fig. 2A) and IL-8 (Fig. 2B) but did not induce significant production of TNF-α (data not shown). The induction of these pro-inflammatory cytokines is specific of Env-ms since Env-syn had no effect.

Taken together, these results indicate that Env-ms exerts a specific pro-inflammatory activity on brain endothelial cells.

Effects of Env-ms on primary endothelial cells

The effects of Env-ms were further studied on primary HUVEC. Recombinant Env-ms induced an increased expression of ICAM-1 (Fig. 3A) similar to that observed previously with HCMEC/D3 cells. Furthermore, HUVECs responded to Env-ms by a strong dose dependent production of IL-8 (Fig. 3C). In contrast, no significant production of IL-6 was obtained after incubation of HUVECs with either Env-ms or TNF-α (Fig. 3B). However, primary HUVECs are able to produce IL-6 in response to LPS stimulation (Fig. 3B). Taken together, these results indicate that Env-ms also induces a pro-inflammatory response of HUVECs but with a slightly different cytokine profile than that of HCMEC/D3 cells.

Implication of TLR4 in Env-ms recognition by endothelial cells

**TLR4 is expressed by HCMEC/D3**

It has been previously shown that Env-ms interacts with the receptor of innate immunity TLR4/CD14, on monocytes and dendritic cells (8); therefore, we investigated whether this pathway may be used by endothelial cells to respond to ENV-ms. TLR4 expression was analyzed in permeabilized HCMEC/D3 cells by fluorescent microscopy which showed that TLR4 mostly colocalized with the Golgi apparatus (Fig. 4A) as has been previously described in other cell types (23,24). Analysis by western blotting demonstrated that in both HCMEC/D3 and HUVECs, TLR4 was expressed as a 150 kDa protein, with a minor band at 120 kDa (Fig 4B). It has been reported in the literature that the heavy form is the fully processed, glycosylated and active form which can be expressed at the cell membrane, while the light form remains intracellular (25). These observations suggest that a fully glycosylated TLR4 form could be expressed by the HCMEC/D3 cells. Treatment of the whole cell extracts with PNGase resulted in the disappearance of the heavy form in favor of the light form (Fig. 4C), showing that the heavy form is glycosylated.
TLR4 knock down abolishes HMEC/D3 response to Env-ms

Subsequently, in order to verify that TLR4 is the receptor implicated in Env-ms recognition, we transfected HMEC/D3 cells with TLR4 targeting siRNAs and assessed the efficiency of TLR4 knock down by western blotting (Fig. 4D). After quantification with ImageJ we measured a 44% decrease of TLR4 expression after two rounds of transfection with TLR4 targeting siRNA when compared to control siRNA transfected cells and a 59% decrease compared to untransfected cells. We then analyzed the effect of reduced TLR4 expression on the induction of ICAM-1 expression and on the production of pro-inflammatory cytokines by LPS, a well known TLR4 ligand, or by Env-ms (Fig 5). The results showed that ICAM-1 expression, induced by either LPS or Env-ms, was significantly reduced (by at least half) in knocked down cells compared to the cells transfected with a control siRNA (Fig. 5A). The specificity of TLR4 silencing by these siRNAs is shown in Fig 5B, which shows that TNFα is still able to induce the expression of ICAM-1 after transfection with these siRNAs. Furthermore, the production of IL-6 and IL-8 cytokines induced by either LPS or Env-ms, was dramatically decreased (by about 90%) after TLR4 knock down as compared to control transfected cells (Fig 5C, 5D). Taken together, these results support the hypothesis that TLR4 is implicated in Env-ms recognition by HMEC/D3 cells.

Discussion

Multiple sclerosis is a chronic neurological disease, whose aetiology remains poorly defined. However, it is well established that inflammatory process in the brain yields to the destruction of oligodendrocytes which build myelin sheaths around axons in the brain and spinal cord (26). Under inflammatory conditions, vascular endothelial cells respond by the secretion of factors and the increase of adhesion molecules that lead to an enhancement of leukocyte adhesiveness and to their migration into tissues (27). The recruitment of activated leukocytes across BBB endothelial cells is a critical step in triggering inflammation and CNS tissue injury in the course of MS (18). Therefore, the initiation of the inflammatory process, along with its outcome on the neuro-immunological context, remains a central point of interest in the understanding of MS. The discovery of the retroviral element MSRV, isolated from the cerebrospinal fluid of a patient with multiple sclerosis (1), has opened new issues about putative microbial contribution in MS physiopathology, reviewed in(6). Several lines of evidence indicate that MSRV could participate to the activation of some immune cells. MSRV and its envelope protein, Env-ms, trigger T-cell receptor Vβ (28) and TLR4 (8), similarly to superantigens such as those encoded by mouse mammary tumour virus (29,30).
Since Env-ms could activate innate immunity through the TLR4/CD14 pathway, we further sought pro-inflammatory activity on endothelial cells which are known to express TLR and respond to TLR signals (27,31). Indeed, we demonstrate that Env-ms is able to activate the vascular endothelium including the brain endothelium in a manner consistent with the fact that MS is an inflammatory disease of the central nervous system. Regarding the activation pathways, our results show that the inhibition of Env-ms induced pro-inflammatory effects is incomplete after TLR4 knock down. This most probably arises from the fact that TLR4 expression is not completely abolished after transfection with siRNAs as observed on our western blotting experiment (Fig 5D). Nevertheless, we cannot exclude the implication of TLR4 co-receptor CD14 (32). Indeed, although CD14 is not detected in HCMED/D3 cells by western blotting, it is known to be present in serum (33,34). In our model, it would be difficult to perform experiments with serum depletion since HCMEC/D3 cells are very sensitive to any modification of culture medium, therefore no definitive conclusion concerning the role of CD14 can be drawn.

One interesting observation of our study concerns the different effects of Env-ms in endothelial cells of different origins. The envelope protein seems to exert a slightly higher pro-inflammatory activity on HCMEC/D3 cells that originates from the brain than on HUVECs that originates from umbilical vein. Indeed, Env-ms triggers the overexpression of ICAM-1 and the production of IL-6 and IL-8 by HCMEC/D3 while only ICAM-1 expression and IL-8 production are strongly stimulated on HUVEC. This is not due to differences in the levels of TLR4 expression between HCMEC and HUVEC since we verified by western blotting that TLR4 was expressed at a similar level in both cell types (Fig. 4B). Concerning the cytokine production, HUVEC are known to produce a much lower amount of IL-6 compared to IL-8 in response to LPS and their response to TNF-α is controversial and depends on culture conditions as already discussed by Mako et al (35). That could explain the absence of IL-6 production after treatment with Env-ms and TNF-α. However, in our conditions, HUVEC are able to produce significant amounts of IL-6 in response to LPS but not in response to Env-ms (Fig. 3C). These variations observed between LPS and Env-ms effects on HUVEC could be explained by a lower affinity of the latter with TLR4 possibly due to structural differences. Finally, in spite of these variations, we show that Env-ms exerts its proinflammatory activity on both types of vascular endothelial cells.

The presence of Env-ms protein was detected in the peripheral blood of most of MS patients as a soluble protein in the serum and as a membrane associated protein at the surface of circulating monocytes and to a lesser extend on B and NK cells (14). Histology of brain tissues of some post mortem MS patients revealed that perivascular lesions contained a large number of macrophages and microglial cells which expressed Env protein as well as HLA-DR (11). Whatever the initial origin of Env-ms, either at the periphery or in the CNS, its presence in both compartments may contribute establishing conditions for neuro inflammatory damage. This is further strengthened by the fact that human oligodendrocyte differentiation is impaired after exposure to Env-ms leading to the reduction
in expression of myelin protein (36). It is striking to note that again in this latter case, Env-ms triggers TLR4 pathway in oligodendroglial precursor cells which respond by the production of proinflammatory cytokines and reactive oxygen species. Interestingly, TLR4 is expressed by other cells contributing to the BBB formation. Firstly, astrocytes have TLR4 but their capacity to respond to its ligands has been a subject of debates. Recently, it has been shown that astrocyte response to LPS stimulation requires CD14 expression (37). Secondly, pericytes, which surround endothelial cells to build capillaries, possess a functional TLR4 that responds to LPS stimulation by the production of proinflammatory cytokines and upregulation of ICAM-1 (38). Although the reactivity of pericytes and astrocytes to Env-ms signal remains to be firmly established, one may consider that the convergence in the BBB of cells expressing TLR4 may favor the particular sensitivity of the CNS to the exposure of TLR4 ligands inducing synergic paracrine signals.

Altogether, these data highlight the importance of the Env-ms / TLR4 pathway in the demyelination and in the inflammation associated to MS (Fig. 6). In the blood, Env-ms can activate on the one hand circulating monocytes, dendritic cells and macrophages and in the other hand vascular endothelial cells leading to the production of pro-inflammatory cytokines, the enhancement of the adhesion of circulating cells to endothelium and then their migration through the BBB into the brain. Env-ms in the brain provokes activation of macrophages, microglial and dendritic cells which orient Th1 response of T lymphocytes. In parallel, Env-ms interferes with oligodendrocyte cells in activating their precursors to produce pro-inflammatory cytokines and in reducing their capacity to build myelin sheaths. Simultaneous inflammatory conditions together with myelinisation defect may favour the rise of myelin specific Th1 T lymphocytes leading to auto-immunity. Obviously, interfering with Env-ms/TLR4 pathway represents a promising therapeutic approach which is currently progressing by the mean of specific anti-Env-ms neutralizing antibodies (39).

In conclusion, our study brings new evidence about the pro-inflammatory properties of MSRV envelope protein, defines the mechanism by which Env-ms stimulates endothelial cells, and reinforces the proposal that MSRV may play a key role in MS pathogenesis and probably in other neurodegenerative disorders, such as schizophrenia (13,40).

A. Flow cytometry analysis of ICAM-1 expression after overnight treatment of HUVECs with TNF-α, Env-ms or Env-syn. B. Analysis of IL-6 production by HUVECs. Cells were treated overnight with TNF-α, Env-ms or Env-syn, IL-6 was measured with ELISA assay. C. Analysis of IL-8 production by HUVECs. Same conditions as for IL-6 measurements. Results represent the mean +/- SE of 2 to 4 independent experiments each performed in triplicate. * p≤0.05; ** p≤0.001.

Figure 4: TLR4 expression in endothelial cells. A. TLR4 colocalizes with the Golgi apparatus. Fluorescent staining of Golgi apparatus (red), TLR4 (green) and nuclei (blue) on HCMEC/D3 cells (not confluent) after fixation with PFA 2% and permeabilization with saponin 0.2%. Negative control is obtained after staining with the secondary antibodies only. Pearson’s correlation coefficient Rr = 0.67 and Mander’s overlap coefficient R = 0.75. Scale bar: 20µm. B. TLR4 is expressed on HCMEC/D3 and on HUVECs. Cells were lysed with the Tris-HCl 50mM, pH 7.5, NaCl 150 mM buffer containing 1% NP40. The presence of TLR4 in the whole extracts is then analyzed by western blotting. C. TLR4 heavy form (150 kDa) leads to a light form (120 kDa) after treatment with PNGase. Whole extracts, prepared with a lysis buffer containing only NP40, were treated with PNGase, or water as negative control, for 2 hours and then analyzed by western blotting. D. TLR4 expression on HCMEC/D3 cells after double transfection with siRNAs targeting TLR4 or control siRNAs; cells were lysed with the Tris-HCl 50mM, pH 7.5, NaCl 150 mM buffer containing 1% NP40. The presence of TLR4 in the whole extracts was then analyzed by western blotting and quantified with ImageJ software. NT: Not Transfected.

Figure 5: Effects of Env-ms are greatly impaired after knock down of TLR4 receptor. A. siRNA transfected HCMEC/D3 cells were stimulated overnight with LPS or Env-ms. ICAM-1 expression was measured by flow cytometry. Cells were either not transfected with siRNA (NT) and not stimulated with LPS or Env-ms (untreated), or transfected with control siRNA (CT siRNA) or TLR4 siRNA and stimulated with Env-me (2µg/mL) or LPS (0.1µg/mL)... Results represent the mean +/- SE of 3 independent experiments each performed in triplicate. B. Same as in A: untransfected cells (NT) or cells transfected with TLR4 siRNA were stimulated with TNFα (100U/mL, 18 hours). C, D. HCMEC/D3 cells were transfected and then stimulated overnight with LPS or Env-ms. Production of IL-6 and IL-8 was measured by ELISA assays. Results represent the mean +/- SE of 2 independent experiments each performed in triplicate. NT: Not Transfected, CT: Control. * p≤0.01; ** p≤0.001.
Figure 6: Schematic representation of the effects of Env-ms.

For Peer Review at Open University Library (PER) on October 22, 2015

Figure A: Bar graph showing the effect of different treatments on IL-6 levels. Treatments include untreated, TNF-100U/ml, Env-ms 0.5µg/ml, Env-ms 1µg/ml, Env-ms 2µg/ml, Env-syn 0.5µg/ml, Env-syn 1µg/ml, Env-syn 2µg/ml. The y-axis represents IL-6 levels in ng/ml.

Figure B: Bar graph showing the effect of different treatments on IL-8 levels. Treatments include untreated, TNF 100U/ml, Env-ms 0.5µg/ml, Env-ms 1µg/ml, Env-ms 2µg/ml, Env-syn 0.5µg/ml, Env-syn 1µg/ml, Env-syn 2µg/ml. The y-axis represents IL-8 levels in ng/ml.
