Dust Profile Assimilation

- Mineral dust is the key radiative forcer in the martian atmosphere.
- Data assimilation: LMD-UK MGCM + observations = best estimate of state [e.g. (1)].
- Vertical dust structure shown by MCS to be more complex than previously assumed [2].
- MCS dust profiles and columns are assimilated to examine impact on the circulation and transport (“3D”), and compared to a MCS column-only assimilation (“2D”) for MY 31.

Figure 1: Zonal Temperatures and Winds

Major difference between assimilation cases is significantly warmer lower-mid atmosphere for the 3D case, due to greater dust representation above 10 km, and enhanced polar warming. Northern polar warming is also shifted higher, potentially heating the lower thermosphere.

In general, 3D case shows strengthened circulation, including as a strengthened southern polar jet; however, northern polar jet mostly unaffected, although strengthened at very high altitudes.

Asymmetry implies vertical dust distribution (e.g. more dust higher up) has most significant effect around “clear” season, when insolation is lower and more high-altitude dust layers are present.

Seasonal asymmetry also related to topography; elevated dust layers act to mitigate topographic asymmetry [3, 4] by providing elevated heating source in northern hemisphere.

Figures:

- Top right: mean meridional circulation for same periods as above zonal mean plots.
- 3D assimilation shows lower dust mass in southern polar vortex despite higher overall.

Mean meridional circulation (MMC) structure sees greatest difference around southern winter, with dramatically intensified Hadley cell. Suggests extra high-altitude dust mitigates topographic effects, as high dust loading can [6]. This has implications for long-term inter-hemispheric transport.

Summary

- Vertical dust structure has significant impact on temperature structure, global circulation, and transport.
- Circulatory impact of increased elevated dust presence appears greatest during lower-insolation times of year: mitigates effect of hemispheric topographic asymmetry and dramatically strengthens the N→S Hadley cell. Stronger Hadley cells overall.
- Reduced near-surface eddy activity; possible explanation for southern dust exclusion.
- TGO will offer a new dataset of dust profiles across a range of martian local times.

Acknowledgements

PMS acknowledges support from the UK Science and Technology Facilities Council under ST/E000114/1 (STFC) and The Open University in the form of a PhD studentship. SRL, MRP and JAH acknowledge support as part of the project UFMARIS (852733) funded by the European Commission’s (EC) 7th Framework Programme. SRL, MRP and JAH also acknowledge the support of the UK Space Agency (STFC) under grants ST/L000642/1 and ST/P001511/1. The authors are particularly grateful for the continued support from the Mars Climate Sounder team, including as a strengthened southern polar jet; however, northern polar jet mostly unaffected, although strengthened at very high altitudes.
