Chapter 2

AC  Collector area (m²)
AS  Storage tank surface area m²)
c  Appropriate specific heat (J Kg⁻¹°C⁻¹)
cp  Volume heat capacity at constant pressure
     (J Kg⁻¹°C⁻¹)
Ch  Initial capital expenditure per house (£)
ET  Total (accumulated sum) of the radiation falling over
     a time period of one month on an inclined surface
     which is above the threshold radiation (J m⁻²)
f  Differential fuel inflation
Fh  Fuel cost per year per house (£)
FR  Collector/heat-exchanger efficiency factor
F'  Collector efficiency factor
i  Discount rate
Ith  Threshold solar irradiance (W m⁻²)
Kh  Repeated capital expenditure per house (£)
L  Monthly total heating demand for space heating and
    hot water (J)
LS  Energy lost from storage tank during the month (J)
MC  Storage heat capacity (J °C⁻¹)
N  Lifetime of hardware (years)
n  Number of years
PVCh  Present value cost per house
Q  Heat energy (J)
QN  Net heat transferred to storage during the month (J)
QT  Solar energy collected during the month (J)
Rh  Running costs per year per house (£)
s  Pebble shape factor
Ta  Ambient temperature (°C)
Tat  Ambient temperature averaged over periods when the
     radiation level is above the threshold (°C)
Tg  Monthly average ground temperature (°C)
Ts  Store temperature (°C)
Ts  Monthly average store temperature (°C)
Tso  Store temperature at the beginning of the month (°C)
\( \Delta T \)  
Temperature change (°C)

\( t_m \)  
Total number of seconds in a month

\( t_t \)  
Total number of seconds collector is in operation in month, i.e. when radiation level is above threshold

\( U_L \)  
Collector overall loss coefficient (W m\(^{-2}\) °C\(^{-1}\))

\( U_S \)  
Storage tank heat loss coefficient (W m\(^{-2}\) °C\(^{-1}\))

\( V \)  
Volume (m\(^3\))

\( \rho \)  
Density (kg m\(^{-3}\))

\( \bar{\tau \alpha} \)  
Monthly average transmittance-absorptance product
## Nomenclature

Chapter 4

A Aperture area, or transparent frontal area of collector (m²)

Cₚ Specific heat of transfer fluid at constant pressure (Jkg⁻¹ · °C⁻¹)

Dₜ Characteristic length (m)

F' Absorber plate (or collector) efficiency factor

Fₚ Collector heat removal factor

g Acceleration of gravity (ms⁻²)

h₁ Convective heat transfer coefficient, duct top to heat transfer fluid (Wm⁻² · °C⁻¹)

h₂ Convective heat transfer coefficient, duct base to heat transfer fluid (Wm⁻² · °C⁻¹)

hᵣ Radiative heat transfer coefficient (Wm⁻² · °C⁻¹)

hₜ Wind heat transfer coefficient (Wm⁻² · °C⁻¹)

H Duct height (m)

I Equivalent normal solar irradiance (Wm⁻²)

k Thermal conductivity (Wm⁻¹ · °C⁻¹)

L Collector length (m)

m Mass flow rate of transfer fluid (Kg s⁻¹)

Nu Nusselt number

Pr Prandtl number

Qₚ Energy per unit time, useful (W)

Re Reynolds number

T₁ Duct top, temperature (°C)

T₂ Duct base, temperature (°C)

Tₐ Ambient air-temperature (°C)

Tₖ Cover temperature (°C)

Tₑ Exit fluid temperature (°C)

Tᵢ Inlet fluid temperature (°C)

Tₘ Mean fluid temperature (Tₑ + Tᵢ)/2 (°C)

Tₚ Average absorber temperature (°C)

Uᵦ Bottom loss heat transfer coefficient (Wm⁻² · °C⁻¹)

Uₑ Edge loss heat transfer coefficient (Wm⁻² · °C⁻¹)

Uₗ Collector overall heat transfer (loss) coefficient (Wm⁻² · °C⁻¹)
\( U_t \)  Top loss heat transfer coefficient (\( \text{Wm}^{-2} \cdot \text{C}^{-1} \))
\( V \)  Wind velocity (\( \text{ms}^{-1} \))
\( W \)  Collector width (m)
\( x \)  Insulation thickness (m)
\( \alpha \)  Absorptance of the collector absorber surface for solar radiation
\( \beta \)  Volume thermal expansion coefficient (\( \text{K}^{-1} \))
\( \varepsilon_c \)  Cover emissivity
\( \varepsilon_p \)  Absorber plate emissivity
\( \eta \)  Efficiency
\( \mu \)  Absolute (dynamic) coefficient of viscosity (\( \text{Kg m}^{-1} \text{ s}^{-1} \))
\( \rho \)  Density (\( \text{Kg m}^{-3} \))
\( \tau \)  Transmittance of the solar collector
\( (\tau \alpha) \)  The product of the absorptance of the collector plate and the transmittance of the cover for normal irradiance
\( \sigma \)  Stefan-Boltzmann constant
Nomenclature

Chapter 5

A \quad \text{Aperture area, or transparent frontal area for collector (m}^2\text{)}

A_c \quad \text{Collector area (m}^2\text{)}

c_p \quad \text{Volume heat capacity at constant pressure (Jkg}^{-1}\text{°C}^{-1}\text{)}

P' \quad \text{Absorber plate (or collector) efficiency factor}

P'' \quad \text{Collector flow factor}

P_1 \quad \text{Correction factor for partial shading of the collector}

P_2 \quad \text{Correction factor for variation of } \tau_a \text{ with the angle of incidence}

P_3 \quad \text{Correction factor for variation in optical properties from normal for diffuse irradiance}

P_R \quad \text{Collector heat removal factor}

h_w \quad \text{Wind heat transfer coefficient (Wm}^{-2}\text{°C}^{-1}\text{)}

I \quad \text{Equivalent normal solar irradiance (Wm}^{-2}\text{)}

I_b \quad \text{Direct solar irradiance in plane of collector (Wm}^{-2}\text{)}

I_d \quad \text{Diffuse solar irradiance in plane of collector (Wm}^{-2}\text{)}

I_m \quad \text{Measured total solar irradiation incident upon the aperture plane of the collector (Wm}^{-2}\text{)}

m \quad \text{Mass flow rate of transfer fluid (Kg s}^{-1}\text{)}

m_t \quad \text{Mass flow rate of leak (Kg s}^{-1}\text{)}

M \quad \text{Fluid capacity of collector (Kg)}

(mce) \quad \text{Effective heat capacity of collector (J °C}^{-1}\text{)}

q \quad \text{Output power per unit aperture area conveyed by the heat transfer fluid (Wm}^{-2}\text{)}

q_u \quad \text{Energy per unit time, useful (W)}

(q_u)_t \quad \text{Energy per unit time under transient conditions (W)}

r \quad \text{Correlation coefficient}

t \quad \text{Time (s)}

T_a \quad \text{Ambient air temperature (°C)}

T_b \quad \text{Average back plate temperature (°C)}

T_e \quad \text{Exit fluid temperature (°C)}

T_f \quad \text{Average temperature of the fluid in the collector (°C)}

T_i \quad \text{Inlet fluid temperature (°C)}
$T_{\text{im}}$  Measured fluid inlet temperature (°C)
$T_m$  Mean fluid temperature ($T_e + T_i)/2$ (°C)
$T_p$  Absorber plate temperature (°C)
$T_{\text{sky}}$  Equivalent black body sky temperature (°C)
$T^*$  Reduced temperature ($T_i - T_a)/I$ (m² °C w⁻¹)
$U_L$  Collector overall heat transfer (loss) coefficient (Wm⁻² °C⁻¹)
$V$  Wind velocity (ms⁻¹)
$\eta$  Efficiency
$\tau\alpha$  Product of the absorptance of the collector plate and the transmittance of the cover for normal irradiance.
$\tau_C$  Collector time constant under flow conditions (s)
$\tau_d$  Cut off time (s)
$(\tau\alpha)_e$  Effective transmittance absorptance product
$(\tau\alpha)_o$  Product of the absorptance and transmittance for normal irradiance
$\Delta T^*$  Time increment
$\theta$  Angle of incidence; degrees from normal
Nomenclature
Chapter 6

FR Collector heat removal factor
hp-c Convection coefficient between absorber plate and cover (Wm⁻²°C⁻¹)
hrp-c Radiation coefficient between absorber plate and cover (Wm⁻²°C⁻¹)
hr-c-a Radiation coefficient from the cover to sky (Wm⁻²°C⁻¹)
hw Wind heat transfer coefficient. (Wm⁻²°C⁻¹)
I Equivalent normal solar irradiance (Wm⁻²)
Ith Threshold solar irradiance (Wm⁻²)
Ta Ambient air temperature (°C)
Ti Inlet fluid temperature (°C)
U Collector heat loss coefficient P'UL (Wm⁻²°C⁻¹)
UL Collector overall heat transfer (loss) coefficient (Wm⁻²°C⁻¹)
εt Thermal emissivity
η Efficiency steady state
η Daily averaged efficiency
η₀ Zero loss collector efficiency, P'(αT₀)
τs Solar transmissivity
(τα) Product of the absorptance and transmittance for normal irradiance

**Figure 5.9** ASHRAE Standard 93-77 Testing Configuration for a Solar Collector when the Transfer Fluid is Air.

**Figure 5.10** Open University Air Collector Testing Configuration.
The experimental data points are shown alongside a theoretical line for comparison. The theoretical model is given by:

\[ T_e = C + \frac{T_{in} - C}{1 - e^{-rt}} \]

where:
- \( T_e \) is the temperature of the system,
- \( T_{in} \) is the initial temperature,
- \( C \) is a constant,
- \( r \) is the rate constant,
- \( t \) is time.

The figure illustrates the response of a structured polycarbonate collector to a step change in insolation from 7.50 W/m² to zero, with a fluid flow rate of 7.2 kg/m²·h.

THE EFFECT OF THERMAL CAPACITANCES ON THE PERFORMANCE OF SOLAR COLLECTORS

Barrie W. Jones and Tadj Oreszczyn
The Open University, Milton Keynes MK7 6AA, UK

A multi-node dynamic computer model of a flat-plate, rear-duct, air-heating solar collector is described, and its verification is outlined. Results from the model are then presented of the daily averaged thermal efficiencies for a variety of simulated ambient conditions pertinent to mid to high maritime latitudes. The collectors differ significantly only in their thermal capacitances. The diurnal variation of insolation produces a modest spread of thermal efficiencies, the lower the thermal capacitance of the collector the higher the efficiency. More rapid fluctuations in insolation produce only a slightly further spread in the thermal efficiencies, though such fluctuations have a more significant effect on peak temperatures.

Keywords: air-heating solar collectors; thermal capacitance effects in solar collectors.

1 INTRODUCTION

Low mass in solar collectors offers the advantage of low construction and installation costs. But the mass also influences the thermal capacitance and hence the thermal efficiency, because even a smooth diurnal variation of insolation prevents a collector from achieving a true steady-state, and the lower the mass the closer the varying conditions are followed. Earlier studies (for example \{1\}, \{2\}, \{4\}) have shown that lowering the mass will improve the thermal efficiency, though perhaps by not very much. However, there seem to be few data on the diurnal performance in various ambient conditions of collectors which differ only in their thermal capacitances. This is particularly the case for air-collectors.

Therefore we have developed and verified a dynamic computer model of a flat-plate, rear-duct, air-heating solar collector. We have used it to obtain daily averaged thermal efficiencies for a wide variety of simulated ambient conditions pertinent to maritime mid to high latitudes. The basic configuration of the collector was varied to yield a wide spread of thermal capacitances. The model is of the multi-node kind, because various studies (for example \{1\}, \{3\}, \{4\}) have shown that simple one-node models are unlikely to give accurate results in non steady-state conditions.

2 THE COLLECTOR MODEL

The collector is of the flat-plate rear-duct air-heating single-cover kind, with dimensions selected to give good performance. It is divided into nodes as shown in Figure 1. (This collector could be complete, or it could be a strip width $W$ of a larger assembly.) Heat balance equations are defined at each node, and the equations are numerically integrated in sequence using the Adams-Bashforth-Moulton predictor-corrector method \{5\}.

The model was tested in a variety of ways, including a comparison of its predictions with the actual behaviour in the laboratory of a flat-plate rear-duct air-heating single-cover collector. In all cases the agreement between prediction and actuality was satisfactory.
RESULTS

5.1 The collectors

Table 1 specifies the collector configurations, and the rear-duct air flow conditions. The basic configuration was selected to give good steady-state performance, the configurations differing only in the thickness of the plate and duct-back (DY1 to DY5 in Table 1). The main effect of these changes in configuration is on the thermal capacitance of the components and hence of the whole collector.

</tr>
</tbody>
</table>

The air flow rate is a compromise between attaining large values of HPA(I) and keeping low the power required to maintain the air flow in the rear-duct. At M = 0.0600 kg s⁻¹ and TI = 303 K (flow 2 in Table 1) this power is 6.4 W. The corresponding pressure drop across the duct is 12 mm water gauge. If it is
assumed that the circulation fan gives a constant volumetric flow rate then at other values of $T_i$ the value of $M$ will be different from $0.0600$ kg s$^{-1}$: at $T_i = 323$ K, $M = 0.0562$ kg s$^{-1}$ (flow 3 in Table 1).

It is also necessary to specify the minimum power that must be delivered by a complete array of collectors in order for the air flow to either be switched on or be sustained. This power must be some multiple of the electrical power required by the fan to circulate air around the whole system incorporating the array. We adopted a multiple of two. In order to estimate the electrical power it is necessary to allow for the efficiency of the fan and for the pressure drop in the whole system. For a modest domestic system we ended up with a minimum power per collector of the sort specified in Table 1 of 128 W for flow 2. For flow 3 PON is slightly less. The values of PON are shown in Table 1. Note that the values of PON are for a 4 m x 1 m collector, and not for the whole array. These values of PON correspond to an air temperature rise of between 2 K and 3 K for the flow conditions specified.

The collector time-constants in Table 1 vary with ambient conditions and with operating conditions, particularly with the air flow rate. The values in the Table are representative for all ambient conditions considered here, and for the various (similar) air flow rates, except for flow 0 (stagnation), in which case the time-constants in Table 1 should be multiplied by about a factor of 5. Note that the time-constants in Table 1 are the 1/e time-intervals following a step change in insolation. However, only in stagnation is the response very close to exponential. Note also that the thermal capacitance of the cover has a relatively small effect, because the cover is coupled to the plate via a rather large thermal resistance.

### 3.2 Steady-state efficiency curve

We obtained a standard steady-state thermal efficiency curve, of the form \( \eta = F_R \left( f(\theta) - U_L (T_i - T_A)/S \right) \) \( \text{(1)} \)

where $f(\theta)$ is such that

\[ SP = f(\theta) \cdot S \]

\( \text{(2)} \)

For the steady state efficiency curve $S$ is beam irradiance normal to the cover, such that $S = 700$ W m$^{-2}$. Furthermore, $T_A = 293$ K, $T_K = 273$ K, $WIND = 1.0$ m s$^{-1}$, $M = 0.0600$ kg s$^{-1}$. These values lie within the ASHRAE specifications for steady-state collector testing \( \text{(6)} \).

In order to obtain the efficiency curve the value of $T_i$ was varied, everything else remaining constant. The outcome is shown in Figure 2 for collector configuration DY1 (Table 1), though the results for DY2 to DY5 are indistinguishable from those for DY1 on the scale of Figure 2. The intercept on the $\eta$-axis, 0.683 gives $F_R$ \( f(\theta) \) (equation (1)). The program yields a value of 0.830 for $f(\theta)$, and therefore $F_R$ is 0.823. The slope gives $-F_R \cdot U_L$, and at low values of $(T_i-T_A)/S$ this is $-2.83$ W m$^{-2}$ K$^{-1}$, giving a value of $U_L$ of 3.44 W m$^{-2}$ K$^{-1}$. The value of $F_R \cdot U_L$ increases as $T_i$ increases $(T_A, S$ constant), largely because the radiative heat transfer coefficients increase with increasing temperature differences, and though $F_R$ decreases it does not offset the increase in $U_L$. These values of $f(\theta)$, $F_R$ and $U_L$ indicate good performance for a flat-plate rearduct air-heating single-cover collector with a selective plate-surface.

We had a "quick look" at the effect of varying the wind speed on the steady-state
temperatures. The effect was fairly modest, because of the large thermal resistance between cover and plate. Wind speed variations will be deferred to a later study.

3.3 Daily-averaged efficiency

The collector configurations DY1 to DY5 were run under conditions flow 2 and flow 3 for a variety of simulated days 21 June (J), 21 March (M), 21 December (D). The simulated conditions of insolation and weather on these days are shown in Figure 3. The ambient temperature TA varies sinusoidally through the day (Figure 3(a)) with an amplitude of 5 K. Note that there are two temperature curves for 21 December, TAD1 and TAD2. The irradiance S consists of a diffuse component from the ground, and of a sky component which can either correspond to clear sky conditions or to overcast diffuse conditions. Figure 3(b) shows some of the various insolations, the prefix S0 denoting the clear sky irradiance normal to the beam, and the prefix S1 the overcast diffuse irradiance on a horizontal surface. In the cases in Figure 3(b) the only variation in insolation is the diurnal envelope shown. By contrast in Figures 3(c) and (d) the insolation flips between the two envelopes shown, the square wave periods being indicated, the conditions remaining diffuse throughout. In clear sky conditions the sky temperature is 20 K below TA, and in overcast conditions it is 10 K below TA. In all cases the wind speed is constant at 1.0 m s⁻¹.

For each "day" an average thermal efficiency was obtained, defined by

\[ \eta = \text{total energy extracted by the air flow in the day/integration of } S \text{ over the day.} \]  

Note that a day spans the time from sunrise to sunset. In no case did a collector deliver energy before or after sunset, and therefore \( \eta \) is never being wrongly evaluated.

In order to plot \( \eta \) on Figure 2 it is necessary to re-define the abscissa \((TI-\text{TA})/S\). TI is constant (303 K or 323 K), and for TA and S the arithmetic mean values for the period sunrise to sunset are taken. The outcome is shown in Figure 2, the results being coded in accord with Table 1 and Figure 3, except that the thermal capacitance configuration DY1 to DY5 is not shown. However, you can see that at each value of \((TI-\text{TA})/S\) there is a column of results, and in every case DY1 is at the top, then comes DY2, and so on, to DY5, though in some cases DY1-DY3 merge on the scale of Figure 2. Clearly, the lower the thermal capacitance the better the performance.

Consider first those cases in which the insolation only varies over the diurnal envelope: this covers the cases (i)-(vi), (viii), (xi). The increase in \( \eta \) is marked in going from the rather massive DY5 to the rather less massive DY4. However, the improvement in going from DY4 to the low mass DY1 is also significant, particularly in marginal conditions (large \( (TI-\text{TA})/S \)). This general improvement with reducing thermal capacitance arises because with a diurnal envelope the slower warm-up of a high mass collector in the morning is not compensated by the slower cool-down in the afternoon. Note that the sinusoidal variations in TA and TK do not make an appreciable contribution to the spread of \( \eta \) with thermal capacitance on the scale of Figure 2.

The advantage of low mass could, in principle, be more marked under intermittent insolation. SID1-SID3 provide such conditions (Figure 3), the periodicities lying within the range of time-constants in Table 1. However, Figure 2 shows that, even in marginal conditions, very little further advantage in low mass is obtained, though DY1-DY3 are more spread out than with the diurnal envelope alone. The
reason for such a slight improvement is that whereas a low mass collector will "follow" the insolation, possibly switching the air flow on and off, a high mass collector, once it has warmed to the point where the air flow switches on, will tend to stay at a fairly constant temperature. The overall effect, for a wide variety of conditions, is that the time-averaged temperatures of the air flow are not very sensitive to the mass. Therefore there is very little difference in the amount of heat extracted. A similar conclusion was reached by Klein et.al [1].

Figure 2 also shows that the values of \( \bar{\eta} \) differ from those of \( \eta \). This is particularly the case at low thermal capacitances, as can be seen from the performance of DY1, which is not very different from that which would have been obtained for a collector of zero thermal capacitance. Two prominent and opposing effects operating here are that for \( \eta \) in Figure 2 the value of \( \delta \) is always zero, thus raising \( \frac{f(\theta)}{\delta} \), and, more importantly, that in insolation conditions which vary, intermittently or otherwise, a collector can "grab" peak insolation, yet entirely miss the corresponding steady state insolation which never reaches such peak values. Low thermal capacitance is again an advantage.

In addition to \( \bar{\eta} \), the daily average of \( T_0 \) was also obtained, such that only those periods were included in which air flowed in the rear duct. In general the lower the thermal capacitance of the collector the higher the daily average, though the improvement from DY5 to DY1 never exceeded 2 K. However, the peak temperatures for DY1 can be up to about 10 K higher than for DY5, the greatest difference occurring in intermittent conditions. In some circumstances this will be an important advantage of low thermal capacitance.

A set of results analogous to those in Figure 2 was obtained for lower flow rates, around 0.02 kg s\(^{-1}\). This is a potentially useful domain, because in spite of the lower thermal efficiencies the values of \( T_0 \) are raised and can reach values such that useful energy can be extracted from ambient conditions which would yield no useful energy at higher flow rates, because of the lower values of \( T_0 \). However the variation of \( \bar{\eta} \) with thermal capacitance (DY1-DY5) was not remarkably different from that shown in Figure 2.

It can be concluded that collectors with low thermal capacitance can have significantly larger thermal efficiencies at non-small daily averaged values of \( (T_1-T_A)/S \) in non-steady insolation, and that this is largely because of the diurnal variation, rather than because of more rapid fluctuations in insolation. Peak temperatures can also be significantly larger at low thermal capacitance, particularly when there are rapid fluctuations in insolation.
