1 INTRODUCTION

The interrelatedness between computer systems, networks, code, and traditional law and legal frameworks continues to pose a number of important and vexed questions. This report will consider one area of the relationship: legal recognition of distributed ledger technology (DLT) or blockchain applications. Specifically, registers appended to blockchains (thereby creating “blockchain registries”), and “smart contracts” executed on blockchains.

Blockchains could shape law as much as law shapes them. The balance between the two may change as so-called ‘blockchain tourism’ abates and ‘practical business applications’ start to appear, albeit in reduced or refined numbers. Yet, a key question remains of whether or not existing legal and regulatory frameworks are capable of comprehending let alone absorbing a wide variety of blockchain applications, concepts, and use-cases without the need to create tailored blockchain laws or standalone blockchain legislation. This issue affects common and civil law jurisdictions alike and is particularly acute regarding traditional contract and property laws and theories, where the latter, in particular, is challenged by the development of novel and tailored blockchain-based assets in the form of tokens.

1 An assumption is made of a general familiarity with blockchain technologies and, therefore, this report will not provide a single definition of DLTs or blockchains.
2 Smart contract is in quotations here due to the debate over what precisely to call this application. For present purposes the nomination “smart contracts” will be used because it is the most common and familiar terminology.
3 This echoes Kevin Werbach and Nicholas Cornell’s view on smart contracts: ‘Smart contracts may or may not transform the world, but they provide real benefits and seem likely to enjoy significant adoption over time. They represent the mature end of the evolution of electronic agreements over several decades’ (Kevin Werbach and Nicolas Cornell. 2017. Contracts Ex Machina. 67 Duke Law Journal 313, p.317). Beyond educational initiatives designed and run by legal services to inform and ensure states of preparedness for entrepreneurs, businesses and governments regarding the potential legal risks surrounding blockchains, there is little evidence that blockchain use-cases are actually transforming legal practices or, more importantly, the formation of laws in many of the jurisdictions in which the technology is presently being explored. The exception to this rule is Estonia, a country that has achieved unprecedented levels of digital infrastructure relying in large part on the Guardtime KSI blockchain and technology stack. See: https://guardtime.com/technology (accessed 15 November 2018)
5 This report will, in part, argue that standalone or tailor-made legislation and regulations is not necessary at present, although greater regulatory monitoring and oversight is required.
6 Tokens and the process of tokenization are both central to the operation of smart contracts and blockchain-based registers. Tokens provide a means of representing different forms of property and assets, and whilst they echo cryptocurrencies in the sense of computationally enabling users to transact on blockchains, they are not generalized mediums of value of exchange or obvious analogues of fiat currencies. In short, unlike cryptocurrencies, a broader idea of tokens does not simply see them as an alternative to cash. Instead, tokens are often tailored to very specific settings (digital environments, communities, or industries), and thus any inherent value a token has for its holder or user is realised within that particular setting.
Tokens play an extensive and critical role in many if not all DLT arenas and applications. Like discussions of smart contracts relative to traditional contracts, tokens require thorough and detailed analysis relative to property law and theory – something that is not possible within the scope of this report. Similarly, pressing questions concerning the regulation of initial coin offerings (ICOs) that enable the development of growing number of blockchain-based applications by, in essence, crowdfunding projects through mass token sales, will not be addressed here, but remain a major concern for lawmakers across different jurisdictions.

For present purposes three comments on tokens, including the role they play in facilitating Decentralized Autonomous Organizations (DAOs), will provide a backdrop to the report, although it is important to note that all three are contestable in many respects. Rachel Botsman focuses on the relationship tokens have to the fundamental ideals blockchains promise, notably the possibly for post-trust transacting: ‘a digitally decentralized, shared ledger that relies on users to power the network by confirming transactions […] means that people who have no particular confidence in or knowledge of each other can exchange all kinds of assets without having to go through a trusted third party such as a lawyer or bookkeeper’8. For Michael J Casey and Paul Vigna tokens are the fuel powering blockchain implementations and a means of redefining and recalibrating existing global economies. The ‘real power of tokens’, claim Casey and Vigna, is that they ‘offered a way to redefine and revalue the very exchange of resources around which economies function’9. In contrast, David Golumbia both highlights the risk of fraudulent behaviour and scams that token economies may facilitate, and the possibilities for erosion of democratic oversight if DAOs, underpinned by blockchain tokenization, proliferate without reasonable government regulatory oversight10.

Returning to issues of legal recognition, evidence from the United States shows a greater number of legislative amendments to State legislation to address blockchains than standalone blockchain legislation, suggesting existing regulatory and legal parameters are, at least for the time-being, proving sufficient11. But, the general lack of specific blockchain laws also means less law to test and refine12.

---

7 See, for example: https://www.fca.org.uk/news/statements/initial-coin-offerings (accessed 3 December 2018)
11 A trackbill.com search returns 63 Bills referencing blockchain presently working their way through State and Federal levels in the US. The 63 Bills are originating in approximately 10 States, including Illinois, Arizona, Vermont, Wyoming, and Hawaii, with 7 individual pieces of legislation at the Federal level. Of the 10 States occupied with drafting blockchain related legislation, the Illinois General Assembly appears to be the only one creating standalone legislation, namely the *Blockchain Technology Act* (IL-HB5553). (accessed 13 November 2018)
12 Out-of-court settlements in cases involving blockchains and cryptocurrencies also play a significant role here, because interpretations of existing laws and to a large extent new laws themselves will only emerge from judicial testing and review. See, for example, the settlement decision between the Securities and Exchange Commission (SEC) and Zachary Coburn of EtherDelta, which the SEC deemed to be operating as an unregistered
This could prove to be a vicious circle in which the opportunities and challenges that blockchain implementation and use pose in many private and public sectors remains undefined and poorly interpreted due to a lack of case-law able to structure and maintain developments.

It may be realistic to assume that blockchains are the next step in the mass socio-economic digitisation that has been underway since the mainstream adoption of the Internet and World Wide Web in the mid to late 1990s, at least in Western countries and the global north. Potentially providing the ‘economic layer the Web never had’\(^{13}\), blockchain-based applications expand the capabilities of the Internet stack and refocus the energies of existing network technologies and electronic working practices. A reasonable legal response is to do exactly the same: to build on and refine the stack of laws already instituted to deal with network technologies, communications, and electronic working practices, as well as, and this is important regarding smart contracts and blockchain registers, testing the authenticity of the law-like effects produced by blockchain applications\(^{14}\).

Central to the ongoing uncertainty surrounding the overall “legality” of blockchains is a lack of robust judicial testing of blockchain-based practices and contexts. As a consequence, the nature of blockchain conduct is not well understood or defined at present\(^{15}\). It will be argued here that in order for legal recognition of blockchain smart contracts and registers (as well as other blockchain-based or decentralized client applications) to satisfy more than minimum or basic legal and regulatory standards, these applications must be tested via detailed analyses of existing laws\(^{16}\). Where lacuna appear in existing rules and principles by virtue of law’s exposure to blockchain, laws pursuant to the specificities of blockchain and blockchain conduct will inevitably take shape.

### 2 Stakeholders

The focus of this report is on legal recognition of smart contracts and blockchain registers within the EU and UK. The globalizing nature of DLTs means, however, that the following discussion will not be limited to those jurisdictions alone.

---

\(^{13}\) Melanie Swan. 2015. *Blockchain: Blueprint for a New Economy*. Sebastopol: O’Reilly, p.vii

\(^{14}\) Legal novelty in the sense of entirely new laws to deal with blockchains is an extreme and unnecessary suggestion. New laws are always created within heterogeneous environments, and blockchains are, therefore, not in a privileged position legally. The matter is arguably different from the point of view of economics. Blockchains may be no more useful or effective than existing ways of working with respect to contracting or registers, but the novelty of the technology creates new markets and thus fosters and drives economic interests.

\(^{15}\) “Blockchain conduct” describes forms of autonomous, or quasi-autonomous behaviour, or methods of management and governance, all of which are produced by or are attributable to blockchain-based applications and implementations. Within this definition of conduct are a range of legal principles, including: performance, duty, obligation, and control.

\(^{16}\) Regarding smart or technological contracts in particular, it is clear that the technology and conceptual developments fall far short of the level of detail necessary to make smart contracts a legitimate and viable contract type.
DLTs and associated applications are being explored, implemented and, therefore, to varying degrees, impacting upon a wide variety of civic (public) and private institutions, markets and sectors. Individual and collective stakeholders for whom legal recognition of blockchain applications is a concern are many and varied, including: governments, international financial and legal services, large corporates, small and medium enterprise (SMEs), entrepreneurs, and individual citizens and communities within the UK, EU member states and internationally.

Individual commercial actors and consortia such as R3 are the driving force behind many blockchain projects. Governments and public sector operations and services may choose (or find necessary) in the near future to adopt blockchain-based registers or smart contracts. While a number of governments, in the UK, US States and Federal level, and EU, are gathering evidence from commercial and academic communities in order to determine a way forward for blockchain initiatives, there is no parity between the public sector and private interests when it comes to research and development of blockchain technology. Yet governments remain the ultimate lawmakers within nation-states and arbiters of legal recognition of information and communications technologies (ICTs), including blockchains, especially where these are shown to have a broad socio-economic reach and impact.

It is vital, therefore, for governments acting in the public interest to establish ex ante regulatory frameworks through which new technologies such as blockchain registers and smart contracts can emerge and develop. Claims that regulations will stifle innovation need only consider whether innovation has, until now, been stifled by existing laws and regulations, with smart regulation that works closely with innovation as the bare minimum standard required.

3 THEMES

The report will cover three main themes:
- Legal recognition

---

18 In the EU there has been, for several years, the desire to harmonize Member State contract laws in order to improve the efficiency of the internal market. Solving the fragmentation and accompanying costs of mismatched approaches to contracting was a central aim of the now abandoned Common European Sales Law (CESL). However, key features relating to the legal basis for a CESL have been reformatted in the Directive on certain aspects concerning contracts for the supply of digital content (COM/2015/0634), in which it is stated that: ‘The existing and upcoming fragmentation creates obstacles for businesses to sell cross-border because they have to incur contract law-related costs. Businesses are also uncertain about their rights and obligations. This has a direct effect on the establishment and functioning of the internal market and negatively affects competition. Given the heterogeneity of the online market for digital content it would be difficult for the market to overcome this fragmentation’.

19 For more on existing and potential regulatory models that might be applied to blockchain see: Robert Herian. 2018. Regulating Blockchain: Critical Perspectives in Law and Technology. London: Routledge
• Smart Contracts
• Registers

Each of the core themes will be illustrated with examples relevant to blockchains (also see Appendix). Further, each will be considered in light of the influence on UK and EU law, as well as broader legal and regulatory frameworks.

The well-spring of contemporary blockchains included an ideological conjunction of anarcho-capitalist and libertarian projects. In a short space of time, however, patterns of blockchain research, development and use have become increasingly normal economically and commercially-speaking\(^{20}\). On that basis, blockchains ought to be subject to normative assessments of legal viability and legitimacy in the first instance, rather than assuming disruption or alienation of existing legal frameworks\(^{21}\).

4 OPEN QUESTIONS

The following ‘open’ questions both reflect the content of the report and lay the foundations for it. Endeavours are made throughout to address if not precisely or always answer the questions, which continue to reflect unresolved or evolving issues and concerns confronting smart contacts and blockchain-based registers, as well as wider legal questions that DLTs and decentralized modes of governance pose.

• Are existing legal and regulatory frameworks capable of absorbing a wide variety of blockchain applications, concepts, and use-cases without the need for tailored blockchain laws or standalone blockchain legislation?

\(^{20}\) Cryptocurrencies such as Bitcoin are exemplars of the mainstreaming of blockchain technologies. While cryptocurrencies remain unstable, largely unregulated marginal economic forms relative to fiat currencies and other commodities, their use nevertheless mirrors and arguably aspires to normative market conditions. Further, the focus of higher education on cryptocurrencies in terms of future employability and economic trends shows the normalization of DLTs in critical and system thought and practice. The Independent reports that, ‘An analysis of the top 50 universities in the world also found that 42 per cent offer at least one class on blockchain or cryptocurrency, with the majority of courses in the US’ (Anthony Cuthbertson, 2018. Bitcoin is on its way to becoming a mainstream currency, study suggests. The Independent. 30 August. https://www.independent.co.uk/lifestyle/gadgets-and-tech/news/bitcoin-adoption-cryptocurrency-mainstream-study-coinbase-facebook-a8514431.html#comments (accessed 14 November 2018).

What combination and balance of legal and technological criteria is necessary for legal recognition to occur?

Should the development of novel laws occur if and when the relevance of existing legal measures have been exhausted or shown to be inadequate?

Ought blockchains to be subject to normative assessments of legal viability and legitimacy in the first instance, rather than assuming disruption or alienation of existing legal frameworks?

Will present tensions between nationalist and transnational political agendas pose significant obstacles to the likelihood of coordination in order to foster a harmonious, global blockchain ecosystem; or will blockchains be weaponized as part of defensive national measures and strategies?

Is there a risk that smart contracts will undermine the validity and integrity of contract law by construing contracts only in terms of complete and fixed arrangements?

How might “post-trust” electronic agreements influence social relations more widely?

Who or what is ultimately responsible (liable, duty-bound) for ensuring the integrity and efficacy of the content (data) in blockchain registries, and how can the problem of rubbish in and rubbish out be mitigated?

Does the (re)introduction of mediatory mechanisms in the form of decentralized arbitration reveal a level of critical inflexibility, especially in smart contracts, which cannot or will not be sufficiently overcome?

How does the tokenization upon which smart contracts and blockchain-based registers largely rely ultimately fit into traditional property law and theory in both common and civil law jurisdictions?

Is the influence and impact of artificial intelligence (AI) and quantum computing sufficiently accounted for in present blockchain development and implementation?

5 LEGAL RECOGNITION

5.1 INTRODUCTION
In this section a number of perspectives on the nature of legal recognition will be offered. Smart contracts or blockchain registers will not be dealt with expressly, instead a broader notion of legal recognition will act as a primer for the remainder of the report.

Before examining legal recognition it is important, briefly, to explore the idea that blockchain applications may not require or, indeed, eschew legal recognition. Notwithstanding this report’s stated aim is to provide insight into legal recognition and, therefore, to extensively argue otherwise would be an exercise in arguing a negative, the grounds from which notions of non-legal recognition stem are vital to the overall picture and, therefore, necessary to address.

For present purposes this report will offer two possible, dialogic routes to the conclusion of non-legal recognition of blockchain applications, although it must be stated that both turn upon a very narrow definition of legal recognition as that
which derives only from formal judicial systems of state. Firstly, it is entirely possible that thorough analyses would conclude that legal recognition is not relevant or necessary in some or most instances of blockchain applications, and alternative methods of self-regulation and enforcement should be allowed to evolve where appropriate, ultimately, to achieve dispute resolution. Secondly, and perhaps more realistically, the decentralized and autonomous (machine-to-machine) capabilities of blockchains negate an a priori requirement for legal recognition. A key example of the latter is arbitration conducted either within or alongside blockchain applications, including smart contract platforms. Embedded or ‘decentralized’ arbitration would enable disputes over particular blockchain transactions to be resolved without traditional legal procedures, frameworks or remedies. OpenCourt, an initiative developed by OpenLaw – a predominately smart contract focused business (see Appendix for details) – aims to provide ‘the first comprehensive step towards […] an end-to-end commercial transaction that incorporates a smart contract powered arbitration system’. OpenLaw underscore their vision of a specific form of smart contract arbitration based on the following rationale:

Agreements incorporating smart contracts will not be immune to disputes and legal challenges. Parties will disagree about the terms governing their performance and disagree on how the smart contract was intended to operate. There also could be bugs in the smart contract itself, creating complications or misaligned incentives. The risk of mistake becomes magnified as smart contracts increasingly interact with outside data provided by trusted oracles like ChainLink but also require humans to perform their terms.

Many of the points raised above will be covered in depth later in this report. It is important to note that, whilst OpenLaw describe a decentralized form of arbitration, their vision does not appear to defeat, nor explicitly want to defeat, the notion of legal recognition formally defined. Rather than disavow legal systems, and by extension the legal recognition those systems facilitate, OpenLaw state that:

blockchains hold out hope to power global universally available judicial systems that deliver low cost and high-quality dispute resolution services online. If implemented, the end result would be game-changing—a globally accessible “online court” where people have an equal opportunity to receive low cost, sophisticated, and transparent justice regardless of their location or creed.

What OpenLaw appear to propose, therefore, is a form of private arbitration conducted on the blockchain, and an analogue of existing off-chain and even off-
line private arbitration frameworks, including those services described under the umbrella of alternative dispute resolution (ADR)\(^{26}\). Notwithstanding the role blockchain plays in facilitating the type of arbitration OpenLaw envision, there is nothing fundamentally new about the proposal on offer, only a recalibration of existing methods and working practices\(^{27}\). Moreover, there is nothing new about the desire to deliver dispute resolution that is more efficient and cost-effective than existing court systems are able to achieve\(^{28}\). Perhaps more importantly, as ADR frameworks generally demonstrate, this form of arbitration does not defeat legal recognition, but is simply an alternative route to it.

### 5.2 Setting the Scene

Law is a product of social relations and a longstanding mediator of disputes, transactions, and agreements. Legal recognition is an ancient and deeply-held philosophical and structural ideal necessary for achieving and maintaining justice between parties (individuals, communities, nations, etc.). Legal recognition both informs and stems from settled jurisprudence, governance models and procedures, as well as sustained conventions, traditions, practices and ethical frameworks, howsoever those come to be defined by an individual state or jurisdiction.

For law to be socially effective it must be able to comprehend (make sense of), and recognise (including the convenience of categorizing) a variety of individual rights, collective enterprises and organisations. In most societies and jurisdictions legal comprehension and recognition of the subject (citizen, claimant, defendant, etc.) or object (database, asset, fund, etc.) involves records, forms, documents, and other material artefacts\(^{29}\). A subject’s rights are not necessarily or always granted using written or pictographic standards such as identity cards, licences, wills or contracts, but are invariably evidenced by them for the purposes of legal procedure. Comprehension and recognition of a subject or object often only occurs satisfactorily in the eyes of the law, therefore, when the ethereality of a right is made manifest in the materiality of an (evidentiary) record. For example, I am born a British citizen and can enjoy the rights and freedoms that entails because I have a birth certificate to prove it.

Similarly, an object is recognised legally if, for instance, and notwithstanding a subject’s claim of a right over it, it meets prescribed legislative definitions or

---

\(^{26}\) The European Commission, for example, provide an extensive list of online alternative dispute resolution forums in each of the member states: https://ec.europa.eu/consumers/odr/main/?event=main.adr.show (accessed 27 November 2018).

\(^{27}\) This point is important because it could arguably apply to a wide range of blockchain use-cases. As a consequence the use of blockchain could be seen as gratuitous and premised only on inter alia ideals of greater security, immutability and transparency of data and transactions without reasonable explanation as to how or why these attributes are either relevant or desirable.

\(^{28}\) In the UK, for example, there have been a number of damning reports in the last thirty years concerning the problems of inefficient and costly justice. See, for example: Jackson, R. 2016. Civil Justices Reform and Alternative Dispute Resolution. Judiciary of England and Wales, 20 September. Available at: https://www.judiciary.uk/wp-content/uploads/2013/03/lj-jackson-cjreform-adr.pdf (accessed 27 November 2018)

\(^{29}\) See, for example: s. 64, Law of Property Act 1925 c.20, which deals in-depth with the production and safe custody of documents, concerns which are highly relevant in the context of blockchain registries.
regulatory standards pursuant to its type, operation or purpose\textsuperscript{30}. While new technologies have enabled inroads into the digitization of bureaucratic processes (notably the advent of electronic signatures as legally enforceable\textsuperscript{31}), there remains a significant amount of, not to mention reliance upon, off-line processes and, perhaps more importantly, paper in maintaining the evidentiary standards necessary for legal recognition. Jean-François Blanchette, for example, maintains that ‘paper records (and paper work) form the material foundation on which the legitimacy and the day-to-day operation of the nation-state rests’\textsuperscript{32}. The fact that something as fundamentally non-digital as a paper record continues to thrive in international bureaucratic processes of all kinds (legal, commercial, financial, etc.) is clearly a major obstacle to the proliferation of systems and networks that rely on digital artefacts.

Legal recognition always involves key externalities, most notably shifts in political and economic climates, or, as in the present instance, the impact of novel technological innovations. Political, economic or technological externalities are invariably reflected in the subsequent formation of legal principles, rules and conduct, but not always in an entirely coherent or obvious way. Hence, law often appears to lag behind or out-of-step with technologies. Gaps (lacunae) in legal knowledge open-up, which in turn fosters uncertainty. A symptom of the lack or failure of legal comprehension and recognition is informal, although not de facto illegal, modes of administration and governance. To be clear, this does not mean that laws do not apply, and the freedom to operate unfettered by the constraints of laws and regulations is often limited for two main reasons.

Firstly, formal law may well apply in such contexts, but can only be described ex post, such as in determinations of illegality. Secondly, communities or systems operating outside of the immediate influence of the formal law nevertheless create and adopt juridical principles, codes of conduct, and methods of arbitration able to perform the formal law in absentia. This includes, for instance, communities or systems that are auto- or self-regulating (autopoietic), where development and

\textsuperscript{30} For example, a “database” is described in s.3A of the Copyright, Designs and Patents Act 1988 c.48 as meaning:
\footnotesize{\textit{a collection of independent works, data or other materials which—}}
\footnotesize{\textit{(a) are arranged in a systematic or methodical way, and}}
\footnotesize{\textit{(b) are individually accessible by electronic or other means.}}
\textsuperscript{31} EU Directive 1999/93/EC provides a Community framework for electronic signatures. As Massimiliano Granieri maintains, however, ‘the Directive does not cover aspects related to the conclusion and validity of contracts or other legal obligations where there are requirements, as regards form, prescribed by national or European Union law, nor does it affect rules and limits, contained in national or European Union law, governing the use of documents (art. 1(2)). In this respect’, Granieri concludes, the impact of Directive on electronic contracting ‘is limited’ (Massimiliano Granieri. 2017. Technological Contracts. \textit{Comparative Contract Law}. Edited by Pier Giuseppe Monateri. Cheltenham: Edward Elgar Publishing Ltd., p.419, fn.34)
evolution of prescriptive and proscriptive measures limits and checks ideas, practices or conduct that offends against the general will of a community or system in which the idea, practice or conduct has originated or to which it has spread.

Legal recognition involves the granting of rights, such as to property, foreshadowed by principles of enforcement (including determinations of illegality and criminality) and mechanisms for restitution or remedy. The conjoined granting and enforcement of rights is a longstanding basis upon which laws rest. Without mechanisms of enforcement and remedy, legal recognition would be a weak and ineffectual principle. Legal recognition can be illustrated in two longstanding and internationally recognised jurisdictions.

Firstly, the settlement of disputes between parties and enforcement of rights. In ‘private law’ dispute resolution, legal recognition turns on the provision and disclosure of documentary and evidentiary standards by parties to a dispute for the purposes of adjudicating rights claims and providing a remedy. Remedies take the form, first and foremost, of damages (money), but also performance (especially in the case of breach of contract), and restitution (returning the parties to the state they were in prior to an agreement).

The outcomes of adjudication further inform and shape the evolution of frameworks for predicting, determining and influencing future conduct and obligations, including offering a means for preventing or dis-incentivizing further disputes. This can occur both through the establishment of formalized, reported precedents, or frameworks and rules for (out of court) settlements. Legal recognition combines settled and agreed principles and rules, with an ability for the laws to react and bend to novelty and contingency within heterogeneous environments. In the context of Australia, Canada, the United States and England and Wales, the latter describes the function of equity and the equitable jurisdiction of Chancery.

Secondly, an act that offends against normative community standards and values prompting a community response in the form of a fine or imprisonment. Like dispute resolution, criminal law does not simply process criminal activity when it occurs, but aims to develop models of prevention as well as cure.

The aim of blockchain registers and smart contracts, like many technologies, should not be to “reinvent the wheel”, that is, to seek to fundamentally remake law, legal practice and frameworks in the image of the electronic or digital. Instead, the aim should be to demonstrate and justify to communities and society at large that electronic alternatives to existing forms and practices are capable of at least meeting the same standards of authenticity, integrity, and legitimacy provided for by prevailing legal standards. Existing legal forms and practices are far from perfect, but they have been hard-won and thoroughly tested. Moreover, they are often highly complex precisely because they have been shaped over generations to meet the dynamism of all social conditions.

5.3 Legal “interface”
A legal interface bridges on- and offline networks and systems, marrying the real world to virtual digital worlds, and enabling at once negotiation, guidance, regulation, and, where necessary, enforcement. As computer protocol a legal

33 In what they call an Integrated Deal-Design Framework, Daniela Alina Plewe and Robert de Rooy consider something akin to a legal interface and its role described here:
interface provides a ‘technique for achieving voluntary regulation within a contingent environment [...] a distributed management system that allows control to exist within a heterogeneous material milieu’\textsuperscript{34}.

The concept of a legal interface echoes the role of an “oracle” insofar as it consolidates information and data. It is vital, however, that an interface is also able to process data against programmed sets of rules relevant to contexts in which the data is being applied. Short of the entire legislative roll of an individual jurisdiction being available for the task of cross-referencing - something that may become possible with artificial intelligence – the legal interface would require a more modest set of rules. There are two possible forms these programmed rules might take. Firstly, a uniform code, such as civil procedure rules used for governing legal proceedings\textsuperscript{35}. Secondly, a constitution, which can, as Vernon Bogdanor maintains, be further interpreted in two ways:

\begin{quote}
The first and most obvious meaning of the term refers to a selection of the most important legal rules regulating the government and embodied in a document promulgated at a particular moment of time, such as the American constitution of 1787 or the French Fifth Republic constitution of 1958. There is, however, a second sense of the term ‘constitution’. A society is distinguished from a mere conglomeration of individuals in that it comprises a group of people bound together by rules: and a constitution is nothing more than a collection of the most important rules prescribing the distribution of power between the institutions of government – legislature, executive and judiciary – and between the individual and the state\textsuperscript{36}.
\end{quote}

A legal interface, like the constitutional format embodied by Bogdanor’s notion of ‘a collection of the most important rules prescribing the distribution of power’, provides a framework for shaping ideas and concepts prior to or in conjunction with implementations to ensure, \textit{inter alia}, that minimum standards of conduct are met by users and participants, and limitations are placed on the exercise of power. To paraphrase Alexander Galloway, a legal interface \textit{qua} constitution is how legal control exists after decentralization\textsuperscript{37}. In that sense the interface is not merely legal or technological, but political. Moreover, it is an arrangement that enables a political solution to the paradoxical intermingling of decentralizing technologies and centralized nation-state sovereignty and jurisdiction.

\begin{quote}
‘Recent developments in the field of legal technology tend to focus on the actual practice of creating contracts, for example, smart contracts [...] a particularly broad view on the context of contracting would be beneficial to such approaches. We firstly propose to consider “high level goals” or “values” of the parties per se, in other words, preferences disconnected from any specific negotiations. These high level concepts serve as regulative ideas providing guidance for the more specific steps in the negotiation’. (Daniela Alina Plewe and Robert de Rooy. 2016. Integrative deal-design: Cascading from goal-hierarchies to negotiations and contracting. \textit{Journal of Strategic Contracting and Negotiation}. Vol. 2 (1-2), pp.19-20)
\end{quote}

\textsuperscript{35} See, for example: https://www.justice.gov.uk/courts/procedure-rules/civil/rules (accessed 27 November 2018)

\textsuperscript{37} Galloway, 2004, p.8
In order to provide a universalizing legal recognition of decentralized transactional models and working practices, the type of constitutionalism inherent in a legal interface could mirror that of approaches to Internet ‘digital constitutionalism’ defined as: ‘a common term to connect a constellation of initiatives that have sought to articulate a set of political rights, governance norms, and limitations on the exercise of power on the Internet’\textsuperscript{38}. Constitutionalism of this sort is not necessarily settled in or by ecosystems of self-regulating commercial actors. Governments in different parts of the world, New Zealand and Italy for example, have shown competence in developing constitutional frameworks for digital practice, which has led in some instances to hybrid constitutionalism\textsuperscript{39}.

Governments, as Santaniello et al point out, ‘have been seeking to perform the fundamental functions of classical constitutionalism in the Internet sub-system, by producing acts directed to the establishment and protection of digital rights, the limitation on the exercise of power on and through digital networks, and the formalisation of governance principles for the Internet’\textsuperscript{40}. It is important to note that, as a universal set of rights enforcement criteria, this type of digital constitutionalism maps across existing international human rights law, rather than interlinking with domestic law in any one nation-state\textsuperscript{41}.

Given the history of Internet regulation and coordination principles being dominated by the United States, ICANN for example, the emphasis on wider international participation and, above all, input into constitutional aims tailored to the likes of blockchain conduct and working practices is welcome. A key question remains, however, of whether the present tensions between nationalist and transnational political agendas pose significant obstacles to the likelihood of coordination in fostering a legal interface \textit{qua} digital constitutionalism of this sort?

### 6 SMART CONTRACTS

This section explores aspects of smart contracts and examines their legitimacy \textit{as} contracts by looking at key features of traditional contract formation and use\textsuperscript{42}.

\textsuperscript{40} Santaniello \textit{et al}, 2018, p.321

\textsuperscript{41} Further to this point, it is also worth noting that, as the two predominant legal systems globally, common and civil law transcend domestic jurisdictions, as a legacy of imperialism and colonialism during the last 400 years. Commonalities prevail between common law jurisdictions such as the UK, US, Singapore, Australia, New Zealand, and Canada despite national constitutions, as they do between a variety of codified civil law jurisdictions such as Brazil, Germany, France, South Africa, Norway, and Russia. Both types of legal system, therefore, already enable a degree of \textit{legal interoperability} between individual nations by virtue of shared juridical histories.

\textsuperscript{42} UK common law will be the lens through which contract formation will be considered in this instance, although many of the rules discussed apply in civil law jurisdictions. In EU terms it is important to note a variety of legislation that has impacted upon electronic contracts, although note smart contracts \textit{per se} Directive on electronic signatures (1999/93/EC): Directive on electronic commerce (2001/31/EC): Directive on contracts
6.1 DEFINITIONS

Traditional contracts can be described as agreements creating obligations enforceable by law, or as the law ‘based on liability for breach of promise’. These definitions crystallize traditional contract law and, importantly, show that contracting does not simply involve creating obligations, it provides a mechanism for situations in which promises fail to materialize or are not performed, or expectations based on a promise are not met.

Do definitions of traditional contract law reasonably or suitably describe smart contracts as we find them today? Contrast traditional definitions with one found in a new blockchain Act presently working its way through the Illinois General Assembly, in which a smart contract is defined as, ‘a contract stored as an electronic record which is verified by the use of a blockchain’, a definition which at first blush suggests that a smart contract is nothing more or less than a traditional contract written to and executed on a blockchain. In other words, the blockchain transforms or translates the traditional into the smart through a process of hybridity. Ethereum founder Vitalik Buterin, speaking in 2016, maintained that: ‘a smart contract is a computer programme that directly controls some digital asset’, a definition that draws on the sort of seamless causality notable in algorithms (“if x, then y”), a causality that is arguably unfamiliar to traditions of contract as well as property law and theory, however, where heterogeneity and contingency form the backdrop to contractual processes.

The wording applied by the Arizona State Legislature is more rigorous: “Smart contract” means an event-driven program, with state, that runs on a distributed, decentralized, shared and replicated ledger and that can take custody over and instruct transfer of assets on that ledger. Norton Rose Fulbright, a global legal services firm who have positioned themselves at the forefront of legal considerations of smart contracts in recent years, add a further dimension: ‘Smart
contracts will often be used to document bilateral obligations between a User and a Counterparty. Smart contracts inherently deal with issues of evidence and intention that are behind some formality requirements – but, until legal systems add rules dealing specifically with smart contract, these formalities will still need to be satisfied.

Initial conceptualizations of smart contracts maintained that the two variations, smart and traditional, were not necessarily supposed to do or perform the same tasks and, therefore, achieve the same legal outcomes. This raises three fundamental issues: firstly, if smart contracts are not challenging, or are incapable of challenging, traditional contract law and theory, then what is the point of them? Secondly, smart contracts may be little more than a niche intervention that will improve cost effectiveness and efficiency in a limited array of contractual scenarios. Massimiliano Granieri claims that, ‘the massive emergence of technology in the realm of contracts and contract law has been interpreted mainly in terms of transaction costs reduction, since technology is instrumental to form agreements in a more expeditious way, regardless of the distance between contractors’, and in this respect ‘the advent of technology in contract law has too often and too simplistically been considered the same as e-commerce’. Thirdly, if smart contracts are not doing what contract law does then isn’t it about time to stop calling them “contracts”?

6.2 First thought, best thought?

Lawyer and technologist Nick Szabo’s elegant introduction to smart contracts relied on the simple mechanism of a ‘humble vending machine’. In that scenario the contract is a straightforward transaction. Let’s briefly revisit the scenario. The role of the purchaser using the vending machine is two-fold: they select a desired product and insert money to cover its advertised price both as payment but more importantly in order to satisfy the necessary stage of contracting known as consideration. At which point the vending machine accepts and processes the payment, and where the payment matches the advertised price releases the product selected to the purchaser, in doing so the vending machine completes performance of the contract. Vending machines perform simple, automated and often seamless transactions. Yet such transactions leave open questions of enforcement if and when the machines fail to convey the product selected by a purchaser. The elegance of the vending machine contract model can only really account for unproblematic transactions and contracts properly performed, not instances of mistake, failure or breach that require a variety of dispute mechanisms and remedies.

Moreover, the vending machine (smart contract) model ignores a truism at the heart of contract law and theory: property does not contract, people do. To embed

---

51 Granieri, 2017, p.408

52 Szabo, 1997
contracts in digitally controlled property as both Szabo and more recently Buterin suggest might presume that breach of contract cannot occur. Equally, it obfuscates and renders uncertain the possibility that parties will receive a remedy in the event a breach does occur or a dispute arises. This potentially changes what Kevin Werbach and Nicolas Cornell have called ‘the posture of litigation’\(^{53}\). ‘Rather than complaining parties seeking fulfilment of alleged promissory obligation’, Werbach and Cornell explain, ‘complaining parties will seek to undo or reverse completed transactions’\(^{54}\). As such, smart contracts do not defeat grounds for remedies in contractual disputes, only shift the emphasis of the remedy from, for example, performance to restitution, thus potentially heralding a rise in restitutionary claims, damages, and overall litigation.

Szabo’s account further concludes that: ‘Smart contracts go beyond the vending machine in proposing to embed contracts in all sorts of property that is valuable and controlled by digital means. Smart contracts reference that property in a dynamic, often proactively enforced form, and provide much better observation and verification where proactive measures must fall short’\(^{55}\). The major caveat in Szabo’s account is the need for property to be ‘controlled by digital means’. This raises the question of how effective smart contracts can be in a world where property is either not controlled by digital means at all, or not by digital means that are compatible or interoperable, or where there is a clear disjuncture between on- and off-line activities or motivations.

These concerns form part of the ‘oracle problem’, relating to the legitimacy and viability of various data sources as well as mechanisms for gathering and consolidating data such as the readings and outputs from ambient or atmospheric sensors (e.g. a meteorological station). The oracle service ChainLink describe their role in providing ‘secure middleware’ for smart contracts as, ‘Building a truly valuable smart contract requires the use of multiple inputs to prove contractual performance, as well as multiple outputs to affect outside systems and/or send payment to complete the smart contract’\(^{56}\).

Importantly, the oracle problem poses questions of who or what ultimately controls and manages vital and potentially valuable input data in these instances. The earlier discussion on the legal interface addressed the same issue to some extent. Realistically, however, there are three common and largely unsurprising options: public state control; private individual or commercial control; or hybrid private/public control. Blockchains do hold the key to further options, namely via decentralized autonomous organizations (DAOs) or corporations (DACs), although both are still, in essence, modes of private, that is, non-state, control.

### 6.3 Are Smart Contracts Sophisticated Enough?

The smart contract definitions cited above describe an ideal type of contract. But they also represent gross oversimplifications that belie the significant complexities of contract law and theory, including the actuality of incompleteness and role of orality in contract formation. For instance, it is not immediately apparent if or how something as basic as the translation of express terms in oral agreements and

\(^{54}\) Werbach and Cornell, 2017, p.376

\(^{55}\) Szabo, 1997

\(^{56}\) https://chain.link/features/ (accessed 30 November 2018)
reasonable intentions of the parties feature in smart contracts. We will return to this matter again shortly. What is more, an ideal always fails to account for flaws, and in smart contract design bugs pose, what Werbach and Cornell call, ‘significant limitation in replacing human enforcement of agreements with software running on the blockchain’; things as they rightly say ‘simply do not always go according to plan’.

Is there a risk that smart contracts will undermine the validity and integrity of contract law by construing contracts only as complete and fixed arrangements? Fundamentally this assumption misses the significance of contractual variations at law and judicial interpretation, as well as key performative and remedial processes such as rescission and rectification that enable the unwinding of agreements.

In other words, it is wrong to view contracts as immutable and for smart contracts to do so, especially with regard to one of the most significant consequences of rescission, namely, treating the contract as though it never came into existence, clearly undermines contract law.

As an institution, contract law helps parties distribute or allocate risk by remaining flexible and contingent, and much of this has to do with an ability to change contracts (rectification); unwind agreements made, inter alia, under duress or because of unconscionable bargains (rescission); put parties back in a position that they would have been in but for the agreement (restitution); or enforce, by order of the court, performance of a contract (specific performance). As previously suggested, restitution is a vital part of the suite of remedies contract law provides, and based on Werbach and Cornell’s claims regarding the future posture of litigation under smart contracts, there is every chance that more not less restitution will be demanded by parties to a dispute in a future of smart contracts.

Many remedies are accompanied by damages relating to the breach of contract, as well as costs for litigation. But the equitable dimension of performance – that an agreement is performed as promised – is a longstanding principle of contract law that reveals agreements are not simply cold, hard transactions between parties freely contracting at arm’s length, but morally binding promises. To undermine or negate remedies for breach of contract is a significant risk to the integrity of smart contracts as contracts, but also disturbs the moral basis upon which much of contract law and theory is predicated, by effectively removing the human element from promissory obligations.

In order to address this issue it is necessary to explore ways in which smart contracts can be more flexible. Ongoing initiatives, for example the ERC1538: Transparent Contract Standard developed by Ethereum smart contract designers, addresses the general inflexibility of smart contracts and seeks to create conditions

---

57 In the broader case of electronic contracts, attempts have already been made to ensure that oral preconditions in contract formation can survive technological change in the form of non-oral modification clauses (NOM). The validity of such clauses has recently been affirmed in the UK by the Supreme Court in Rock Advertising Limited v MWB Business Exchange Centres Limited [2018] UKSC 24

58 Werbach and Cornell, 2017, p.365

59 Cardozo J in his judgement in the New York Court of Appeals in Beatty v Guggenheim Exploration Co (1919) 225 NY 380 maintained: ‘Those who make a contract, may unmake it. The clause which forbids a change, may be changed like any other. The prohibition of oral waiver, may itself be waived. Every such agreement is ended by the new one which contradicts it’.

60 As per Lord Wilberforce in Johnson v Agnew [1980] AC 367
whereby variations in contract terms (“functions”) are possible61. Addressing the vexed issue of smart contract immutability qua flexibility is vital if they are to better align with traditional contract law62. But it is also clear that in changing the fundamental immutability of smart contracts a desirable aspect of them, namely the ability for parties or individuals to execute contracts without having to trust one another, is eroded. As the author of the Standard maintains:

Immutable, trustless contracts cannot be improved, resulting in increasingly inferior contracts over time. Contract standards evolve, new ones come out. People, groups and organizations learn over time what people want and what is better and what should be built next. Contracts that cannot be improved not only hold back the authors that create them, but everybody who uses them. In some cases immutable, trustless contracts are the right fit. This is the case when a contract is only needed for a short time or it is known ahead of time that there will never be any reason to change or improve it63.

Mistakes, as they say, do happen. But in contract law mistakes assume particular significance with regard to contract frustration64. Courts (and the common law more generally) aim to uphold contracts when and where possible, but this is not always possible or desirable on the facts. Such mechanisms and processes demonstrate that contract is, however, flexible, contingent, and, perhaps above all else, a reflection of the inherent messiness of human enterprise. This, for some technologists, may be reason enough to find a “solution” to the “problem” of traditional contract law.

But, it is incumbent on smart contract designers to remember that contracts do not only exist in an immature state such as vending machine transactions. Nor is it desirable for contracts to do so if a balance between the express and consensual execution of rules-based agreements and the moral obligation of promise and performance are to remain intact65. Put another way, contract is a legal norm that

61 Nick Mudge. 2018. ERC1538: Transparent Contract Standard #1538. 31 October. https://github.com/ethereum/EIPs/issues/1538 (accessed 17 November 2018) – This standard addresses the following technical issues:

- A way to add, replace and remove multiple functions of a contract atomically (at the same time).
- Standard events to show what functions are added, replaced and removed from a contract, and why the changes are made.
- A standard way to query a contract to discover and retrieve information about all functions exposed by it.
- Solves the 24KB maximum contract size limitation, making the maximum contract size of a transparent contract practically unlimited. This standard makes the worry about contract size a thing of the past.
- Enables an upgradeable contract to become immutable in the future if desired.

63 Mudge, 2018

64 See, for example: Great Peace Shipping Ltd v Tsavliris, The Great Peace [2002] 4 All ER 689

65 This points to the role of laws of equity and restitution, especially within Anglo-American common law jurisdictions, both of which work in and around the law of contract in order to ensure inter alia that a fair and reasonable balance is maintained between the bargaining powers of parties and that grounds for unjust enrichment or unconscionable bargaining are mitigated.
has successfully underwritten and influenced many social structures, not just the individual transactions to which they referred. Therefore, the question of how “post-trust” electronic agreements might influence social relations more widely is one that ought to be taken seriously.

6.4 NATURAL VS COMPUTER LANGUAGE

From the point of view of legal services, but also wider business interests, the key to the legitimacy and scalability of smart contacts turns on the matter of contractual language. In particular, the relative legibility and accessibility of natural language contracts (English as a common standard for international trade and consumer contracts for example), compared with the computer language or code of smart contracts. Under s. 7 of the Unfair Terms in Consumer Contracts Regulations 1999 (SI 1999, No. 2083), for instance, written contracts must be expressed in plain, intelligible language, and “coded” smart contracts do not necessarily meet this requirement.66

Recall the Illinois General Assembly’s definition of smart contracts: ‘a contract stored as an electronic record which is verified by the use of a blockchain’. In this example it is entirely possible for a traditional, natural language contract to form the basis of the electronic record, in the form of, for example, a scanned paper contract or PDF. In this case the natural language of contract is not disturbed by the intervention of smart protocols, and retrieval and interpretation of the contract could still remain a familiar task to the lawyer or paralegal.

Compare this to Vitalik Buterin’s definition: ‘a smart contract is a computer programme that directly controls some digital asset’. In this case, no documentary form of a contract exists outside of the electronic environment purposefully established for its execution. The smart contract is either embedded in the property being conveyed or is formed at the moment of transaction and “written” in code. Whilst this may cause potential problems of contract legibility and intelligibility for the parties subject to it, smart contracts do appear to satisfy another key stage in traditional contract formation, namely, by establishing an enforceable pre-written promise.69

Usually promises are binding if made orally or reflected by a particular form of conduct that evidences the promise or intentions of the parties to form a contract. In the case of smart contracts as defined by Buterin, however, a promise (or even an effective agreement) exists (latently) in the property subject to transaction, and as such the promise exists not unlike implied terms or clauses in traditional

---

68 Buterin, 2016
69 In the common law context it is especially important that this aspect of smart contracts is tested with regard to a variety of remedial actions, notably resulting and constructive trusts and estoppel. Resulting and constructive trusts, for example, have proven to be important safeguards in cases where a contract was obtained by fraudulent misrepresentation (Lonrho plc. v Fayed (No. 2) [1992] 1 WLR 1; El Ajou v Dollar Land Holdings plc [1993] 2 All ER 717)
contracts. Instead of *ex post* adjudication in order to interpret and expressly define an implied term, that is, a term that was always already in the agreement, a smart contract executes on the basis that the agreement is always already valid.

The pre-written stage in contract formation raises one final important question: the ability of smart contracts to mirror good faith principles and the reasonable expectations of parties. As computer code or script, smart contracts do, by their very nature, privilege the written or documentary form as evidence of contract formation. Yet the matter of oral agreements (promises made) as binding based on evidence of the intention of the parties is a long settled and general rule applicable to most types of property. How can smart contracts ensure this rule remains in place, including associated considerations of good faith?

If the answer is that oral agreements or good faith can be “coded” into smart contracts by, for example, a lawyer or notary trained in smart contract formation, then, once again, it must be asked whether this can be considered an improvement upon existing practices or a mere reinvention of them. Moreover, there is specific tension that arises between good faith principles or requirements, as a standard for fair dealing within contractual contexts, and the promise of smart contracts (and blockchains more generally) to foster *trustless* or post-trust transacting regimes. If smart contracts negate good faith by design, this places a heavy burden on smart contracts to maintain conditions in which good faith is no longer necessary. This presupposes that smart contracts can radically alter conduct in ways that continue to reflect good faith even in the absence of the principle.

### 6.5 Conclusions

An increasing number of peer-to-peer, domestic and international agreements, modes of exchange and transaction are being explored in light of smart contract compatibility and viability. It has been stated that a successful smart contract regime requires and insists in equal measure on the digitization of property, notably, as discussed earlier, via tokens. Without this state of affairs smart contracts cease to offer an autonomous technological solution that is wide-ranging. Instead, and as present conditions dictate, smart contract use must accommodate off-line, real-world legal conditions that accordingly satisfy normative standards of contract formation, performance, and remedial action in order to have any real value. Smart contracts are presently viable in tandem with existing contractual regimes, resulting in hybrid and concomitant (traditional and smart) contracting regimes. Like traditional contracts or other promissory formats and systems (fiant

---

70 Implied terms are distinguished from express terms. Express terms are ‘actually recorded in a written contract or openly expressed at the time the contract is made. But there are cases in which the law implies a term in a contract although it is not expressly included therein by the parties. An implied term may be a condition, a warranty or an intermediate (innominate) term’ (*Chitty on Contracts*, 2018, at 14-001).

71 For example, in the UK, s. 53 of the *Law of Property Act* 1925 c.20 stipulates that written agreements must be used to create or dispose of an interest in land; to declare a trust of land; or in dispositions of equitable interest under a trust.

72 For a detailed overview of some of these concept and use cases please see the Appendix.

73 From the first inception of the smart contract concept to one of the latest statements of a viable commercial form, the need to change not only the nature of contract but also property has been identified as a critical factor in enabling smart contracts to operate in a practicable way. See, for example: Szabo. 1997; Mattereum. 2018. *Mattereum Protocol: Turning Code into Law*. https://www.mattereum.com/ (accessed 12 November 2018)
currency for example), the ultimate value of smart contracts will only really derive from the belief that others will accept them as part of a process of transaction or exchange.

Further, contrary to the notion of smart contracts “disrupting” existing contract law and theory, they must instead satisfy a high level of interoperability with the processes and procedures of verification defined by traditional contract law and theory. As Beale *et al* explain: ‘contract law’ is used to mean the whole collection of rules which apply to contracts, and these may include many rules that are not ‘contractual’ in the sense of being based on a promise to do something”74. This forms part of the determination of legal recognition that smart contracts must meet if they are to be legitimate, and whilst the dynamic nature of contract means it is ‘always developing ad sometimes changing rapidly as new problems confront the courts and legislature’75, a transition to smart contracts, if and when it occurs, is unlikely to sweep away all vestiges of traditional contract law.

The problem of bridging real and virtual worlds (the oracle problem), as well as bringing laws of contract and property into *digital harmony*, remain major obstacles for smart contract design and implementation within domestic jurisdictions and internationally76. Moreover, the question of whether smart contracts ought to be construed as or considered contracts *simpliciter* remains highly contentious77. Instead, smart contracts might best be understood as a new *type* of contract within an overall suite of contract law, rather than an alternative to or replacement for traditional contracts. It is clear from a legal standpoint that smart contracts do not provide a wholly viable alternative to existing forms of contract, nor, indeed, pose a threat78. Smart contracts are an immature judicial

---

74 Beale *et al*, 2008, p.3
75 Beale *et al*, 2008, p.8
78 For example, *Chitty on Contracts* (a vital reference work on contract law) does not mention smart contracts in the latest (October 2018) edition, only electronic documents
form incapable of fulfilling most of the conditional requirements of traditional contract law and theory. Although complacency on the part of lawyers is unwise and potentially misguided.

Smart contracts may provide corresponding opportunities and create markets for a small number of specialists. It is important, therefore, to recognise the rhetoric and especially hyperbole surrounding smart contracts, and subject lobbying interests to reasonable scrutiny. Smart contracts may serve special interests, but not a wider public interest upon which centuries of contract theory is built. Put another way, is there enough firm evidence that contract law needs to be, or actually will be, “disrupted” by smart contracts? Furthermore, can this be achieved without corresponding and far reaching changes to property law and cultures of ownership?

7 REGISTERS & REGISTRIES

An existing web of legislative and regulatory provisions and procedures, rules and principles command a wide range of transnational and trans-jurisdictional registration practices. The promise of greater network decentralization offered by blockchain, allowing for simultaneity in information and data sharing between jurisdictional authorities may alter and, indeed, improve the ways in which registry systems operate in the future. Decentralization may improve trans-jurisdictional collaboration but it does not automatically negate the necessity for a high degree of centralized control of registries within individual jurisdictions, nor allow for an abdication of responsibility for maintaining robust and reasonable audit practices. The key role of state maintained blockchain registers would be to ensure sticky ownership notifications that fix (time-stamped and immutable) to commodities, assets, funds, investments, indeed anything subject to registration for the purposes of administrative oversight. Further, this once again focuses attention on the matter of tokens as the basic asset class available to blockchain registries.

7.1 A HYPOTHETICAL TAX LIABILITIES REGISTER

Imagine a register that auto-defines and enforces the tax liabilities of individuals or corporations either domestically or trans-nationally. Appended to a specified blockchain registry, the register would enable a direct link to be maintained between a specific token or asset and either the legal or beneficial owner of that

79 The following EU regulations provide examples of registers that may be attractive options for translation onto blockchain, primarily due to the transnational and trans-jurisdictional nature of the regulatory subject matter: Regulation aiming to establish a common framework for business registers (No. 177/2008): Regulation concerned with the registry of ships, or rather the transfer of them between registers (No 789/2004); Regulation No. 166/2006 is concerned with the establishment of a European Pollutant Release and Transfer Register; Directive 2017/1132 has a section on company registers; Trade mark Directive 2015/2436 refers to registers but not a specific system; Insolvency regulation refers to the requirement of publicly accessible registers (2015/848)

80 The type of blockchain (public, private, permissioned, permissionless, hybrid, etc.) required for such a registry would need to be decided.
asset for the purposes of tracking tax liabilities. Liabilities would auto-enforce based on a range of events, including conveyance by sale or gift, or transfer of ownership as part of a will or in trust. Echoing tokenization, as the digitisation of all property types required for the successful scalability of smart contracts, a tax liabilities register would run smart contract-like scripts that could identify, collect and enforce a quantum of liability associated with specific assets according to a prescribed tax code.

Can a register of this sort have legal force, and, importantly, who or what is ultimately responsible (liable, duty-bound) for ensuring the integrity and efficacy of the content on electronic registers in blockchain registries, and how to avoid the problem of rubbish in and rubbish out? Governments rely upon the competencies of centralized departments, institutions and agencies, such as Her Majesty’s Revenue and Customs (HMRC) in the UK, to ensure databases and registers such as the one described above offer an effective means of combating tax evasion and avoidance and safeguarding the collection of vital revenues.

Decentralizing these responsibilities using blockchains, in the sense that the tax code would be embedded within the asset, could prove more efficient and secure than existing methods. Transparency with regard to certain liabilities could also be maintained, although this would not necessarily require a public blockchain. Transparency, in this instance, would engender a two-way street: honest and fair dealing of assets on the part of the legal or beneficial owner of the asset, and honest and fair calculation of liabilities on the part of tax authorities.

### 7.2 Different but the same

The effectiveness of a tax liabilities register, as noted above, relies on much the same principles required for the scalability and efficacy of smart contracts. Smart contracts in conjunction with blockchain-based registers, therefore, could help make individuals and businesses economically expedient, and keep them honest. In an honest tax regime individuals and corporations would choose to navigate ownership of fluid property and assets, including deriving rental income from those tokenized assets, using smart contracts, whilst simultaneously enabling an index of tax codes to read the status of a particular asset and collect revenues accordingly. Formalized association of the two regimes, in other words, is technologically possible, but it must also be desirable to enforce that association politically as well as legally, and the primary aim of doing so would be to affect a particular mode of blockchain conduct.

Concomitance of smart contracts with smart contract enabled registers in the hypothetical example of collecting and enforcing tax liabilities echoes real-world systems of provenance, attribution and enforcement in present use-cases found, for example, in the arts and music. Accurate and fair attribution of intellectual property using blockchain is seen as a significant step forward in protecting the rights of artists, and allowing artists to create opportunities to generate and derive reasonable income and royalties from their work\(^8\). Registers that clearly define

---

ownership and provide regulatory oversight are entirely practicable and merit consideration in an array of public (civic) and private (commercial) contexts.

In order to escape niche implementation only, blockchain-based registers, like smart contracts, require a general reappraisal and potential revision of normative cultures of property ownership in order to be scalable and effective as autonomous systems. The alternative is a patchwork of hybrid forms involving existing, non-blockchain-based systems, tokens, assets, and databases that will at best dilute and at worst undermine or negate any gains that blockchain systems promise. It is possible that small-scale blockchain projects are able to start necessary paradigm shifts required in different sectors, but this will not be a short-term measure\textsuperscript{82}. Furthermore, the likelihood that blockchains, as a technological \textit{tour de force}, are superseded in the interim cannot be discounted.

A major factor concerning blockchain-based registers is the ability to erase appended records and data, especially in jurisdictions where data subjects have a so-called ‘right to be forgotten’. In particular, the General Data Protection Regulations (GDPR) could prove highly problematic for public registers but not necessarily for private registers appended to permissioned blockchains. Of the new rights under GDPR, the right to be forgotten (Art. 17) is one which does not sit comfortably with what for many stakeholders are core and desirable features of blockchain, namely the ability of ‘immutability’ to create ‘transparency’ in order to foster ‘trust’. It is important to note that ‘erasure’ is not an absolute right to be forgotten under the terms of the legislation however, and if, for example, the data involves defence of a legal claim or has overriding public interest then a data controller can refuse to comply with the right. Maxwell and Salmon describe the issue as follows:

One of the design features of blockchain architecture is that transaction records cannot be changed or deleted after-the-fact. A subsequent transaction can always annul the first transaction, but the first transaction will remain in the chain. The GDPR recognises a right to erasure. The broad principle underpinning this right is to enable an individual to request the deletion or removal of personal data where there is no compelling reason for its continued processing. What constitutes “erasure” is still open to debate. Some data protection authorities have found that irreversible encryption

\textsuperscript{82} An analogy can be drawn here with internet retail or e-commerce versus offline retail, and blockchain-based registers versus off-chain ‘electronic records’ and databases or even paper-based registries. In the US in 2017 e-commerce accounted for only 9% of all retail sales. Whilst this figure is increasing (12.4% expected by 2020) and has made a number of e-commerce companies such as Amazon very wealthy and powerful, it has taken more than 20 years to reach this relatively modest market share. The retail culture in the US is, in other words, not yet dominated by e-commerce and will not be dominated by it for several years to come based on present projections, despite the relative maturity of today’s digital infrastructure compared with 10 years ago. The change is occurring, but only very steadily because the major shift required is not technological, it is cultural.
constitutes erasure. In a blockchain environment, erasure is technically impossible because the system is designed to prevent it. The right to be forgotten linked to the erasure of personal data strikes at the heart of the immutability of blockchain-based registers. Following the logic above, once immutability falls due to mechanisms for undoing or unwinding chains, does this bring into question the level of transparency and the ability to foster trust that the promise of blockchains rests on?

8 OBSTACLES

The aim here is to briefly outline known and unknown obstacles facing smart contracts and blockchain-based registers. The obstacles described also reflect on DLTs more broadly and thus potentially capture a variety of applications that use DLTs beyond those explicitly discussed in this report.

8.1 KNOWN

A number of key issues relating to blockchains have emerged following the relative maturation and pervasive use of cryptocurrencies, as well as tokens that enable tangible and intangible property to be represented on the blockchain, exchanged and transacted, globally. Three main obstacles can be highlighted here (in no particular order).

Firstly, issues of cost, speed, scalability and ultimately, the long-term security of blockchains. The IOTA Foundation’s development of a rival to the blockchain called the Tangle is predicated on the notion that blockchains are slow, expensive, and, as a consequence, will not scale sufficiently for commercial or civic purposes. Cryptokitties, a very popular game based on the Ethereum blockchain, also revealed problems with both speed and scalability of the blockchain as it struggled to support a huge growth in users. Further, while the cryptography underlying blockchains is seen as one of its strongest attributes compared with traditional or existing data storage, rapid developments in quantum computing are likely to undermine the robustness of blockchain architectures.

Secondly, the environmental and climatic costs due to a massive growth in computing power needs. Mass cryptocurrency mining, notably in China, has revealed that stringing together multiple computers in order to enable blockchain-based applications to operate on an industrial scale uses (much like many

84 https://www.iota.org/research/meet-the-tangle (accessed 16 November 2018)
85 https://www.cryptokitties.co/ (accessed 3 December 2018)
conventional means of production) a great deal of electricity and energy. If blockchain-based systems and projects are to be or remain environmentally sustainable, therefore, a significant priority must be to ensure infrastructure developments do not augment and contribute to deteriorating global environmental conditions.

Thirdly, issues of interoperability and a general fluidity and harmonization across a range software (and hardware) has long plagued digital network design and scalability, and the same fate confronts blockchains. Arguably, the matter has been tackled on the Internet to a large extent by economic means rather than technological solutions, namely via monopolisation (centralized control) of different digital methods, platforms, and artefacts (including data). The role monopoly plays is economic, but it equally affords a sense and utility of harmony between methods, platforms, and artefacts previously seen as divergent by virtue of competition · the consolidation and proliferation of Google services is an example of this. Ethereum have been significant in addressing issues of blockchain interoperability by providing designers with an opportunity to develop decentralized applications (dApps), including smart contracts using a uniform token standard that can represent different assets, whether fungible or non-fungible (most recently ERC-1155), which bridge and enable interactions between the blockchains and other, conventional (off-chain), technologies and properties.

The blockchain attributes of decentralization, disintermediation and distribution are all powerful ideals which ought, at least in theory, undermine monopoly and discourage monopolistic interests. The reality, however, is somewhat different. The fundamental issue at hand is that there is not a single, uniform blockchain. Since the contemporary emergence of DLTs in the form of the Bitcoin blockchain in 2008 · a public blockchain predicated on ideals of post-trust transparency and true peer-to-peer functionality – there has been a significant expansion of both public (permissionless) and private (permissioned) blockchains organized around similar but not the same principles or aspirations. Decentralization, in this sense, begins to look like fragmentation based on a wide variety of different interests.

88 For a further discussion on the relationship between blockchain and climate change, see: https://unfccc.int/news/how-blockchain-technology-could-boost-climate-action (accessed 3 December 2018)
89 For a more thorough examination of these arguments see: Nick Srnicek. 2017. Platform Capitalism. Cambridge: Polity
91 The present development of different blockchains echoes the evolution and fragmentation of the Internet. Milton Mueller has argued that Internet fragmentation has largely been driven by a ‘mismatch’ between cyberspace ideals of unfragmented space and the real territorial demands of nation-states and legal jurisdiction. For Mueller this is best illustrated in the field of cybersecurity where jurisdiction has been forced upon an otherwise unfragmented space in order to ensure the integrity of national interests are secured and maintained. Whilst Mueller is correct in his assessment of jurisdiction in this regard, the idea that cyberspace is a priori unfragmented is not true. This is because it fails to account for the role and equally fragmentary influence of commercial, private interests defending commercially lucrative digital territories. See: Milton Mueller. 2017. Will the Internet Fragment? Cambridge: Polity

28
8.2 **Unknown**

By their very nature pin-pointing and even describing unknown obstacles or, similarly, unintended consequences is harder than the inverse. As Chris Reed suggests with regard to the ‘law of unintended consequences’ that shadow ICT legislation and regulation, the ‘tendency to concentrate on the intended consequences of regulation often means that it potential to produce unintended consequences is overlooked’. Therefore, this sub-section will simply and briefly list some potential unknown obstacles, especially with regard to legal services as facilitators of frameworks and mechanisms governing legal recognition.

- Minimum requirement/level of combinatory techno-legal skills and the impact on employability
- Adjusting entrenched law and procedural frameworks to new technological methods.
- Adjusting for technology incompatibilities and inconsistencies within legal services and beyond.
- Mid to long term impact on legal education and services.
- Mid to long term impact on business and society from shifts in practices and principles of contract and property law and theory.

9 **Conclusions**

‘Blockchain technology is a highly reliable witness to ideas and events, in that sense it bears no relation to the fallibility of human memory whilst maintaining an inescapable dialogue with it. Blockchain records and (re)presents data, appends and witnesses, (de)materialises and (re)configures, and does so in ways that both reflect existing Internet capabilities and intensifies them, for purposes that are primarily economic, but nevertheless result in social, cultural and political consequences.’

Blockchains offer trans-national and trans-jurisdictional ways of working, including the possibility of machine-to-machine “invisible” functionality, fully autonomous systems underpinned by tokens and self-ex Executing code (DAOs or even decentralized commons\(^\text{94}\)), perpetual scripts (smart contracts?), the Internet of Things (“IoT”), artificial intelligence (AI), or a combination of all of these. Problems persists however. In jurisdictions such as the UK and EU (as a Union and individual member states) there is lingering uncertainty over blockchains due to an overall lack of jurisprudence (i.e. case-law, legislation, regulations or directives), and a lack of focus on or understanding of blockchain conduct.

Blockchain conduct requires lawmakers to focus not on the technology or applications alone, but on those who engage with or rely on them (developers, designers, users, consumers, ‘prosumers’, data providers, data managers, etc.).

\(^{93}\) Herian, 2018, p.31

\(^{94}\) The idea of Decentralized Autonomous Organizations (DAOs) famously devalued in 2016 when a hack exploiting a software vulnerability drained a fund of approximately $50 million in cryptocurrency. From a legal standpoint the ‘theft’ from the fund did not arguably breach any rights (was not, therefore, a *de facto* fraudulent act) because the smart contract at the heart of the organization executed as it was supposed to.
Generally speaking it is correct to assume that technology does not break laws, breach contracts or contravene rights, people do. This means lawmakers must remain in-step with conduct produced by technologies such as blockchains and not allow legal recognition to lag behind.

Legal or, more specifically, regulatory lag can be attributed to a number of factors, some of which are more obvious than others. For example, whilst the agility of innovationism versus the grinding gears of legal evolution is often cited as a main reason for regulatory lag, the predominance of self and smart regulatory measures, including “wait and see” and “wait and monitor” provisions in the EU context, that aim to give space to innovation and not stifle entrepreneurial enterprise, are arguably also contributing to a failure for public, regulatory bodies to remain fully engaged and thus not simply keep pace but potentially set it.

“Wait and see” might satisfy economic demands, as well as ideological ones, in the immediate term, but is not a reasonable measure in the medium to long-term without suitable mechanisms in place to guarantee actual implementations based on legal recognition, oversight, and certainty. This is especially the case where risk and public interest intersect in public expenditure initiatives to support innovation. Innovation conducted on a basis of civic benefit or improvement (for example, blockchain-based registers of patient records), ought to be accompanied by legal certainty, not only to guide implementations, but more importantly offer informed redress in the event of a dispute, fault or breach.

At present it is not viable for smart contracts and blockchain-based registers to act autonomously. Instead, a high level of hybridisation is necessary in order to surmount a disjuncture, most notably, between technological aspirations and legal (property, contractual, etc.) norms and cultures. This means smart contracts working in tandem with on- and offline, and on- and off-chain, transactional modalities. Further, it means blockchain-based registers acting like, rather than superseding, traditional databases or similar electronic archives. As a consequence, significant new laws and regulations tailored to smart contracts and blockchain-based registers are yet to emerge. When they do, however, the rules and principles that underpin them must be well informed, robust, and equitable.

---

95 The EU seem to be moving towards regulatory standards interlinked with technical standards. In a recently adopted EU non-legislative resolution on DLTs and blockchains, the Commission and the national competent authorities are encouraged to ‘swiftly build up technical expertise and regulatory capacity, allowing for rapid legislative or regulatory action if and when appropriate’ (John Salmon. 2018. EU adopts non-legislative resolution on DLTs and blockchain. Hogan Lovells. 8 November. https://www.hlengage.com/eu-adopts-non-legislative-resolution-on-dlts-and-blockchains (accessed 15 November 2018))

96 See, for example: https://medicalchain.com/en/ (accessed 19 November 2018). Use cases such as medical records stored on blockchain emphasise individual control over data. At first blush ‘taking back control’ may seem an incontestable good, but the ramifications to the individual are, I suggest, far from conclusive and may even assume, incorrectly, a high level of expertise and knowledge, as well as psychological competence to individually or personally administer massive amounts of personal data.
APPENDIX

1 LEGAL “INTERFACE”

- Constitutional format
- Embedded jurisdiction
- Granting “contextualized” legal rights
- Enforcement/control procedures and mechanisms
- Automated/hybrid regulation
- Importance of defining a vocabulary
