**Could life, or its signatures, survive the journey from Mars to Phobos?**

- Studies have suggested that impact ejecta from Mars, which would represent Mars’ surface over its geological history, could have accreted onto Phobos [2].
- Mars ejecta could constitute up to 0.05% of Phobos’ regolith, where ~200 ppm was deposited in the last 10 million years [2-4].
- If life existed on Mars during its ancient past, evidence may have been altered or destroyed by subsequent geological processes [5].
- Impact ejecta, which could have contained ancient martian biosignatures, may have been deposited onto Phobos and could still be preserved today [5,6] - lithopanspermia.

**Without direct samples, regolith simulants are vital.**

- Currently, all we know about Phobos comes from remote sensing.
- Future sample return missions (i.e. JAXA’s Martian Moons eXploration mission MMX) are in development.

**Demand for Phobos simulants:**

- Mission tests – landing/take off mechanisms, microgravity sampling techniques and spacecraft exhaust contamination – Planetary Protection.
- Science - *in-situ* resource utilisation potential assessment of Phobos and NEAs [7] and testing the Mars-Phobos lithopanspermia hypothesis.

**An ESA concept study funded the design and production of a Phobos regolith simulant. Feasibility dictated that two simulators were needed to meet all the physical and chemical requirements of potential uses [4]**

**Compositional simulant (Phobos-1C)**

- Inherent density of compositional simulant is comparable to Phobos’ regolith.
- Crushed particles subsequently sieved into three size fractions <425 μm, 1.2-3.3 mm and >5 mm for future experiments.

**Physical simulant (Phobos-1P)**

- Using size distribution power law: \( N(D) = k (D_0 + D_b)^{-x/b} \)
- Power law index \( x \), turnover index \( D_b \), cut-off index \( b \), constant \( k \) [12]
- Physical simulant mimics Phobos’ hypothesized average regolith grain size of ~1 mm [13], with <300 μm depletion [14].

**Physical simulant mineralogy**

- Quartz & Calcite, consistent with concrete.
- Crushed aggregate concrete *Topcrete* chosen for the physical simulant because it is physically comparable to Phobos [8] with a density of 1.67 ± 0.05 g cm\(^{-3}\).
- Density 1.67 ± 0.05 g cm\(^{-3}\)
- Compressive strength 3.5 MPa

**Future aims:**

- Further characterisation: XRD (NHM)
- Run impact experiments using the high-velocity All-Axis Light-Gas Gun to test the survival and modification of biosignatures.
- Assess the accuracy and reliability of current biosignature identification and analysis techniques.

**Acknowledgements:** The funding by STFC of a studentship [ST/S005014/1] to ZSM is acknowledged.

**Chemical and textural characterisation of two Phobos regolith simulants**

Currently, samples returned from Phobos have a Planetary Protection status of “unrestricted Earth return”. If impact experiments show significant survival of biosignatures, this status may require re-assessment, with implications for future missions, such as MMX! [1]
