PREVALENCE OF ODOMETERS IN CELLULAR AUTOMATA

ETHAN M. COVEN, MARCUS PIVATO, AND REEM YASSAWI

Abstract. We consider left permutive cellular automata $\Phi$ with no memory and positive anticipation, defined on the space of all doubly infinite sequences with entries from a finite alphabet. For each such automaton that is not one-to-one, there is a dense set of points $x$, which is large in another sense too, such that $\Phi : \overline{\{\Phi^n(x) : n \geq 0\}} \to \overline{\{\Phi^n(x) : n \geq 0\}}$ is topologically conjugate to an odometer, the “$+1$” map on the countable product of finite cyclic groups. We identify the odometer in several cases.

Introduction

In this paper we show that for a certain class of one-dimensional cellular automata $\Phi$ defined on the space of all doubly infinite sequences with entries from a finite alphabet, there are many sequences $x$ such that $\Phi : \overline{\{\Phi^n(x) : n \geq 0\}} \to \overline{\{\Phi^n(x) : n \geq 0\}}$ is topologically conjugate to an odometer. We then investigate the size of the set of such points.

We use the most concrete definition of odometer. Let $(s_1, s_2, \ldots)$ be a sequence of integers greater than 1. The $(s_1, s_2, \ldots)$-adic odometer is the “$+1$” map $\tau$ defined on the compact, abelian group $Z(S) = \prod_{n \geq 1} Z/s_n Z$ where $S = (s_1, s_2, \ldots)$, addition is “with carrying” and $\tau : Z(S) \to Z(S)$ is defined by $\tau(z) = z + (1, 0, 0, \ldots)$. When $S$ is the constant sequence $(s, s, \ldots)$, $\tau : Z(S) \to Z(s)$ is called the $s$-adic odometer and denoted $\tau : Z(s) \to Z(s)$.

Key words and phrases. odometer, cellular automaton.

This work was done in Spring 2005 while the second and third authors were van Vleck Visiting Professors of Mathematics at Wesleyan University. The first author wishes to thank the lovely summer weather on Cape Cod for delaying the submission of this article.
Odometers are also called adding machines. They are characterized by being minimal, having uniformly equicontinuous powers, and having rational point spectrum with respect to Haar measure [2].

A cellular automaton is a continuous, shift-commuting self-map, defined on the space of all doubly infinite sequences with entries from a finite alphabet. It is well-known that every cellular automaton $\Phi$ is given by a local rule $\varphi$: for some $r \geq 0$, for all $x$, and for all $i, -\infty < i < \infty$,

$$[\Phi(x)]_i = \varphi(x_{i-r}, x_{i-r+1}, \ldots, x_{i+r}).$$

$\Phi$ has anticipation $r > 0$ if and only if there exist $t_{-r}, t_{-r+1}, \ldots, t_{r-1}$ such that $\varphi(t_{-r}, t_{-r+1}, \ldots, t_{r-1}, \cdot)$ is not the constant function. $\Phi$ has no memory if and only if $\varphi(t_{-r}, t_{-r+1}, \ldots, t_r)$ depends only on $t_0, t_1, \ldots, t_r$. Finally, $\Phi$, with no memory and anticipation $r > 0$, is left permutive if and only if for every $t_1, \ldots, t_r$, $\varphi(\cdot, t_1, t_2, \ldots, t_r)$ is a permutation of the alphabet.

Composition of local rules is defined so that if $\varphi$ is the local rule of $\Phi$, then $\varphi^2$ is the local rule of $\Phi^2$, etc. Thus if $\varphi = \varphi(t_0, t_1, \ldots, t_r)$, then

$$\varphi^2(t_0, t_1, \ldots, t_{2r}) = \varphi(\varphi(t_0, t_1, \ldots, t_r), \varphi(t_1, t_2, \ldots, t_{r+1}), \ldots, \varphi(t_r, \ldots, t_{2r})).$$

Left permutive cellular automata are a well-studied class. Among their pleasant properties are that they are finite-to-one, map the space of all doubly infinite sequences onto itself, and preserve Bernoulli $(\frac{1}{s}, \frac{1}{s}, \ldots, \frac{1}{s})$-measure, where $s$ is the size of the alphabet. See, for example, [3, 4].

The statements of the theorems and their proofs involve the one-sided cellular automaton $\Phi_R$, defined on the space of all one-sided sequences by the same local rule as $\Phi$.

We show for left permutive cellular automata with no memory that are not one-to-one, a trivial necessary condition for $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ to be topologically conjugate to an odometer is also sufficient. We show that the set of such points $x$ is dense, and is large in another sense we make precise. We identify the odometer in a number of cases.

Note that odometers are one-to-one maps, while in most cases the cellular automata we consider are not.

1. Existence of Odometers

In this section we show for left permutive cellular automata $\Phi$ with no memory, a trivial necessary condition on $x$ with $(x_1, x_2, \ldots)$ $\Phi_R$-fixed for $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ to be topologically conjugate to an odometer, namely that $\{\Phi^n(x) : n \geq 0\}$ is infinite, is also sufficient.
Theorem 1. Let $\Phi$ be a left permutive cellular automaton with no memory, defined of the space of all doubly infinite sequences with entries from a finite alphabet. If

- $\{\Phi^n(x) : n \geq 0\}$ is infinite and
- $(x_1, x_2, \ldots)$ is $\Phi_R$-fixed,

then $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \to \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to an odometer.

Proof. Let $k_1$ be least such that $(x_{-k_1}, x_{-k_1+1}, \ldots)$ is not $\Phi_R$-fixed and let $s_1$ be least such that $(x_{-k_1}, x_{-k_1+1}, \ldots)$ is $\Phi^{s_1}_R$-fixed. ($s_1$ exists because $\Phi$ is left permutive.) As a model of the inductive step, let $k_2 > k_1$ be least such that $(x_{-k_2}, x_{-k_2+1}, \ldots)$ is not $\Phi^{s_1}_R$-fixed and let $s_2$ be least such that $(x_{-k_2}, x_{-k_2+1}, \ldots)$ is $\Phi^{s_1,s_2}_R$-fixed. Continue.

We show that $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \to \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to the $(s_1, s_2, \ldots)$-adic odometer. To do this we show that the map of $\{\Phi^n(x) : n \geq 0\}$ into $\mathbb{Z}(S)$, $S = (s_1, s_2, \ldots)$, defined by

$$\Phi^n(x) \mapsto \text{“base-}S^n\text{” expansion of } n,$$

and its inverse are uniformly continuous. (The map is well-defined because $\{\Phi^n(x) : n \geq 0\}$ is infinite.)

For $i \geq 0$, the “base-$S^n$” expansions of $m$ and of $n$ agree at places $0, 1, \ldots, i$ (a measure of closeness in $\mathbb{Z}(S)$) if and only if $\Phi^m(x)$ and $\Phi^n(x)$ agree at places $-k_i, -k_i + 1, \ldots, 0$. Since $(x_1, x_2, \ldots)$ is $\Phi$-fixed, $\Phi^m(x)$ and $\Phi^n(x)$ agree at places $-k_i, -k_i + 1, \ldots, 0$ if and only if they agree at places $-k_i, -k_i + 1, \ldots, k_i$ (a measure of closeness in the space of all doubly infinite sequences). Therefore the map is uniformly continuous on $\{\Phi^n(x) : n \geq 0\}$ and its inverse is uniformly continuous on the image of this set.

Let $\Psi$ be the extension of this map to a homeomorphism defined on $\text{cl}\{\Phi^n(x) : n \geq 0\}$. Since the image of $\{\Phi^n(x) : n \geq 0\}$, the non-negative integers, is dense in $\mathbb{Z}(S)$, $\Psi$ maps $\text{cl}\{\Phi^n(x) : n \geq 0\}$ onto $\mathbb{Z}(S)$. Since $\Psi \circ \Phi = \tau \circ \Psi$ on $\{\Phi^n(x) : n \geq 0\}$, $\Psi \circ \Phi = \tau \circ \Psi$ on $\text{cl}\{\Phi^n(x) : n \geq 0\}$ as well. \qed

Remark. It follows from the proof that if the odometer is the $(s_1, s_2, \ldots)$-adic odometer and the alphabet has $s$ letters, then every $s_i \leq s$.

Corollary. Let $\Phi$ be a left permutive cellular automaton with no memory, defined of the space of all doubly infinite sequences with entries from a finite alphabet. If

- $\{\Phi^n(x) : n \geq 0\}$ is infinite,
- $(x_1, x_2, \ldots)$ is $\Phi_R$-periodic with least period $q > 1$, and
- $\Phi^q : \text{cl}\{\Phi^{nq}(x) : n \geq 0\} \to \text{cl}\{\Phi^{nq}(x) : n \geq 0\}$ is topologically conjugate to the $(s_1, s_2, \ldots)$-adic odometer,

then $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \to \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to the $(q, s_1, s_2, \ldots)$-adic odometer.
Proof. The topological conjugacy of \( \text{cl}\{\Phi^q_n(x) : n \geq 0\} \) to \( \mathbb{Z}(s_1, s_2, \ldots) \) is the extension of the map \( \Phi^q_n(x) \mapsto \text{"base-(s_1, s_2, \ldots)" expansion of } n \). Extend this map to a map \( \Psi_0 \) of \( \{\Phi^q_n(x) : n \geq 0\} \) into \( \mathbb{Z}(q, s_1, s_2, \ldots) \) by \( \Psi_0(\Phi^q_n(x)) := (v, w_1, w_2, \ldots), \) where \( n = uq + v, 0 \leq v \leq q - 1, \) and \( \Psi_0^q(x) = (w_1, w_2, \ldots) \). Then \( \Psi_0 \) extends to a topological conjugacy of \( \text{cl}\{\Phi^q_n(x) : n \geq 0\} \) onto \( \mathbb{Z}(q, s_1, s_2, \ldots) \).

2. Prevalence of Odometers

In this section we identify senses in which the set of points \( x \) such that \( \Phi : \text{cl}\{\Phi^q_n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^q_n(x) : n \geq 0\} \) is topologically conjugate to an odometer is large.

It is clear from looking at the form of the local rules of the powers of cellular automata that every positive power of a left permutive cellular automaton with no memory is left permutive and has no memory. This not the case with positive anticipation, although we do have the following.

Lemma. Let \( \Phi \) be a left permutive cellular automaton with no memory and positive anticipation, defined on the space of all doubly infinite sequences with entries from a 2-letter alphabet. Then \( \Phi^q_n \) has positive anticipation for every \( n \geq 1 \).

The lemma is not true for larger alphabets, as shown by the following example. Consider the cellular automaton \( \Phi \), defined on the space of all doubly infinite sequences with entries from \( \{0, 1, 2\} \), and local rule \( \varphi(t_0, t_1) = t_0 \), except that \( \varphi(0, 1) = 2 \) and \( \varphi(2, 1) = 0 \). Then \( \Phi^2 \) is the identity map.

That this is essentially the only example is shown by the following

Lemma. Let \( \Phi \) be a left permutive cellular automaton with no memory, defined on the space of all doubly infinite sequences with entries from a finite alphabet. Then \( \Phi^q_n \) has positive anticipation for every \( n \geq 1 \) if and only if \( \Phi^q_m \) is not the identity map for every \( m \geq 1 \). In particular, if \( \Phi \) is not one-to-one, then \( \Phi^q_n \) has positive anticipation for every \( n \geq 1 \).

Proof. Suppose that \( \Phi^q_n \) has zero anticipation. Since \( \Phi^q_n \) is left permutive, it is a permutation of the alphabet. Therefore \( \Phi^{kn} \) is the identity map for some \( k \geq 1 \).

Theorem 2. Let \( \Phi \) be a left permutive cellular automaton with no memory and positive anticipation, defined on the space of all doubly infinite sequences with entries from a finite alphabet. Then exactly one of the following statements holds.

1. For every \( \Phi^q_{R \text{-fixed }} (z_1, z_2, \ldots) \), the set of points \( x \) such that \( x_i = z_i \) for every \( i \geq 1 \) and \( \Phi : \text{cl}\{\Phi^q_n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^q_n(x) : n \geq 0\} \) is topologically conjugate to an odometer is a dense \( G_\delta \) subset of \( \{x : x_i = z_i \text{ for every } i \geq 1\} \).
(2) For every $\Phi_R$-fixed $(z_1, z_2, \ldots)$, the set of points $x$ such that $x_i = z_i$ for every $i \geq 1$ and $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \to \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to an odometer is empty.

If the alphabet has two letters or if the cellular automaton is not one-to-one, then (1) holds.

Proof. It suffices to show that if $\Phi^n$ has positive anticipation for every $n \geq 1$, then (1) holds.

Since $\{x : x_i = z_i \text{ for every } i \geq 1\}$ is a complete metric space, by Theorem 1 and its Corollary it is sufficient to show that the set of points in this set with finite $\Phi$-orbits is a countable union of sets which are closed and nowhere dense in this set.

The set of points in $\{x : x_i = z_i \text{ for every } i \geq 1\}$ with finite $\Phi$-orbits is

$$\bigcup_{i \geq 0} \bigcup_{j \geq 0} (\Phi^{-i}(\text{Fix}(\Phi^j)) \cap \{x : x_i = z_i \text{ for every } i \geq 1\}).$$

For each $j \geq 1$, $\text{Fix}(\Phi^j) \cap \{x : x_i = z_i \text{ for every } i \geq 1\}$ is a closed and nowhere dense subset of $\{x : x_i = z_i \text{ for every } i \geq 1\}$. It is nowhere dense because $\Phi^j$ has positive anticipation, and so any point in $\text{Fix}(\Phi^j) \cap \{x : x_i = z_i \text{ for every } i \geq 1\}$ can be changed arbitrarily far to the left so that it still is in $\{x : x_i = z_i \text{ for every } i \geq 1\}$ but not in $\text{Fix}(\Phi^j)$.

Since every $\Phi^i$ is left permutive and hence a self-homeomorphism of $\{x : x_i = z_i \text{ for every } i \geq 1\}$, each set in the double union above is a closed and nowhere dense subset of $\{x : x_i = z_i \text{ for every } i \geq 1\}$.

It follows from the two lemmas preceding the theorem that if the alphabet has two letters or if the cellular automaton is not one-to-one, then (1) holds.

□

Corollary. Let $\Phi$ be a left permutive cellular automaton with no memory and positive anticipation, defined on the space of all doubly infinite sequences with entries from a finite alphabet. Then exactly one of the following statements holds.

(1) For every $\Phi_R$-periodic $(z_1, z_2, \ldots)$, the set of points in

$$\bigcup_{0 \leq k \leq q-1} \{x : x_i = [\Phi^k(z)]_i \text{ for every } i \geq 1\},$$

where $q$ is the least period of $(z_1, z_2, \ldots)$, such that $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \to \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to an odometer is a dense $G_\delta$ subset of

$$\bigcup_{0 \leq k \leq q-1} \{x : x_i = [\Phi^k(z)]_i \text{ for every } i \geq 1\}.$$
(2) For every $\Phi_R$-periodic $(z_1, z_2, \ldots)$, the set of points in
\[
\bigcup_{0 \leq k \leq q-1} \{ x : x_i = [\Phi^k(z)]_i \text{ for every } i \geq 1 \},
\]
where $q$ is the least period of $(z_1, z_2, \ldots)$, such that $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ is empty.

If the alphabet has two letters or if the cellular automaton is not one-to-one, then (1) holds.

Proof. Each set $\{ x : x_i = [\Phi^k(z)]_i \text{ for every } i \geq 1 \}, \ k = 0, 1, \ldots, q - 1$, contains a dense $G_\delta$ subset. Since these sets are closed and pairwise disjoint, the union of the dense $G_\delta$ sets is a dense $G_\delta$ subset of $\bigcup_{0 \leq k \leq q-1} \{ x : x_i = [\Phi^k(z)]_i \text{ for every } i \geq 1 \}$.

Another sense in which the set of points $x$ such that $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to an odometer is large is given by the following.

**Theorem 3.** Let $\Phi$ be a left permutive cellular automaton with no memory and positive anticipation, defined of the space of all doubly infinite sequences with entries from a finite alphabet. Then exactly one of the following statements holds.

1. The set of points $x$ such that $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to an odometer is dense in the space of all doubly infinite sequences.

2. The set of points $x$ such that $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to an odometer is empty.

If the alphabet has two letters or if the cellular automaton is not one-to-one, then (1) holds.

Proof. By [1] the set of $\Phi$-periodic points is dense in the space of all doubly infinite sequences. The result then follows from the elementary fact that if for every $i$, $Y_i$ is dense in $X_i$, and if $\bigcup X_i$ is dense in $X$, then $\bigcup Y_i$ is dense in $X$.

3. **Identifying the Odometer**

In this section we identify the odometers in Theorem 1 and its Corollary for certain cellular automata. We assume, without loss of generality, that when $s$ is the size of the alphabet, the alphabet is $\mathbb{Z}/(s)$, the ring of integers modulo $s$, and we restrict our attention to left permutive cellular automata with no memory and anticipation $r > 0$, whose local rules can be written in the form $t_0 + \theta(t_1, \ldots, t_r)$. Recall that when the alphabet is $\mathbb{Z}/(2)$, every positive power of such a cellular automaton with positive
anticipation has positive anticipation. It is easy to see that when the alphabet
is $\mathbb{Z}/(2)$, the local rule of every left permutive cellular automaton with no memory
must be of this form. That this is not true for larger alphabets is shown by the
example at the beginning of Section 2.

**Theorem 4.** Let $\Phi$ be a left permutive cellular automaton with no memory and
anticipation $r > 0$, defined on the space of all doubly infinite sequences with entries
from $\mathbb{Z}/(p)$, $p$ prime, and whose local rule is $t_0 + \theta(t_1, \ldots, t_r)$ for some function $\theta$. If

- $\{\Phi^n(x) : n \geq 0\}$ is infinite and
- $(x_1, x_2, \ldots)$ is $\Phi$-fixed,

then $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to the
$p$-adic odometer.

**Proof.** As in the proof of Theorem 1, let $k_1$ be least such that $(x_{-k_1}, x_{-k_1+1}, \ldots)$
is not $\Phi$-fixed and let $s_1$ be least such that $(x_{-k_1}, x_{-k_1+1}, \ldots)$ is $\Phi^s_1$-fixed. Since
$\Phi_R(x_{-k_1}, x_{-k_1+1}, \ldots) = x_{-k_1} + i\theta(t_{-k_1+1}, \ldots, t_{-k_1+r})$ and $\theta(t_{-k_1+1}, \ldots, t_{-k_1+r}) \neq
0, s_1 = p$. Continuing as in the proof of Theorem 1, we find that $s_2 = s_3 = \cdots = p$. \qed

**Corollary.** Let $\Phi$ be a left permutive cellular automaton with no memory and
anticipation $r > 0$, defined on the space of all doubly infinite sequences with entries
from $\mathbb{Z}/(p)$, $p$ prime, and whose local rule is $t_0 + \theta(t_1, \ldots, t_r)$ for some function $\theta$. If

- $\{\Phi^n(x) : n \geq 0\}$ is infinite and
- $(x_1, x_2, \ldots)$ is $\Phi$-periodic with least period $q > 1$,

then $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to the
$(q,p,p,\ldots)$-adic odometer.

**Theorem 5.** Let $\Phi$ be a left permutive cellular automaton with no memory and
anticipation $r > 0$, defined on the space of all doubly infinite sequences with entries
from $\mathbb{Z}/(p^n)$, $p$ prime, and whose local rule is $t_0 + \theta(t_1, \ldots, t_r)$ for some function $\theta$. If

- $\{\Phi^n(x) : n \geq 0\}$ is infinite and
- $(x_1, x_2, \ldots)$ is $\Phi$-fixed,

then $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to the
$p$-adic odometer.

**Proof.** In the proof of Theorem 4, the least $i > 0$ such that $(x_{-k_1}, x_{-k_1+1}, \ldots)$ is $\Phi^i_R$-
fixed is $p^{m_1}$ for some positive $m_1 \leq m$. Continuing this way, we get that $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to the $(p^{m_1}, p^{m_2}, \ldots)$-adic
 odometer, which is topologically conjugate to the $p$-adic odometer. \qed
Corollary. Let $\Phi$ be a left permutive cellular automaton with no memory and anticipation $r > 0$, defined on the space of all doubly infinite sequences with entries from $\mathbb{Z}/(p^n)$, $p$ prime, and whose local rule is $t_0 + \theta(t_1, \ldots, t_r)$ for some function $\theta$. If

- $\{\Phi^n(x) : n \geq 0\}$ is infinite and
- $(x_1, x_2, \ldots)$ is $\Phi_R$-periodic with least period $q > 1$,

then $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to the $(q, p, p, \ldots)$-adic odometer.

Theorem 6. Let $\Phi$ be a left permutive cellular automaton with no memory and anticipation $r > 0$, defined on the space of all doubly infinite sequences with entries from $\mathbb{Z}/(p)$, $p$ prime, and whose local rule is $at_0 + \theta(t_1, \ldots, t_r)$ for some function $\theta$ and some $a \neq 0, 1$. If

- $q$ is least such that $a^q = 1$,
- $\{\Phi^n(x) : n \geq 0\}$ is infinite, and
- $(x_1, x_2, \ldots)$ is $\Phi_R$-fixed,

then $\Phi : \text{cl}\{\Phi^n(x) : n \geq 0\} \rightarrow \text{cl}\{\Phi^n(x) : n \geq 0\}$ is topologically conjugate to the $(q, p, p, \ldots)$-adic odometer.

Proof. Use the proof of the Corollary to Theorem 1. \qed

The reader is invited to state and prove for Theorem 6 the result corresponding to the Corollary to Theorem 4.
